fice, as well. Some of the smaller Picinae species, such as the Little Woodpecker in the Neotropics, have been found to nest in bamboo, and the larger Bamboo Woodpecker regularly does so in South-east Asia, from where there is good evidence that the latter's congener, the Pale-headed Woodpecker, also occasionally excavates its nest-hole in a bamboo stem. Another Neotropical picid, the White Woodpecker, sometimes uses holes among rocks, and such versatile species as the American Red-headed Woodpecker not only breed in natural holes, but will readily nest also in buildings and in other artificial structures, including pumps.

Cacti are perfect tree substitutes for quite a few melanerpine species. Indeed, the White-fronted Woodpecker, the Hispaniolan Woodpecker, the Golden-cheeked Woodpecker (*Melanerpes chrysogenys*), the Red-crowned Woodpecker, and the Grey-breasted and Gila Woodpeckers habitually nest in cacti. Among the flickers in the genus *Colaptes*, the Gilded Flicker sites its nests most frequently high up in giant saguaro cacti (*Carnegiea gigantea*) and less commonly in cottonwood (*Populus deltoides*) and willow (*Salix*) trees. Striped Woodpeckers, too, sometimes breed in cacti, and the Ladder-backed Woodpecker, in its xeric habitat with limited numbers of suitable nest trees, uses as nest-sites not only fence posts, but also yuccas (*Yucca*), agaves (*Agave*) and large cacti. Strickland's Woodpecker will also utilize agaves.

Even the large nests of certain arboreal social insects can serve as nesting substrates for woodpeckers. In the Neotropics, the Golden-green Woodpecker frequently breeds in such structures and the Black-necked and Green-barred Woodpeckers are known to do so at least occasionally. More notably, the Asian Rufous Woodpecker regularly digs its breeding holes into the football-sized nests of tree-ants of the genus *Crematogaster* that are still occupied by the ants and their brood; this woodpecker may in the same way exploit the nests of other ants, such as *Plagiolepis* species, but it also excavates cavities in trees and stubs. In South America, the Pale-crested Woodpecker not uncommonly digs its holes into the nests of arboreal ants or termites, and so, too, does its relative the Blond-crested Woodpecker, while the Cuban Green Woodpecker also occasionally uses arboreal termitaria for its own nesting purposes. Among the African picids, the Buff-spotted Woodpecker is known to excavate its nest not only in wood, but also, and frequently, into the arboreal nests of termites or ants.

This kind of behaviour, in which the nests of social insects are exploited by birds for their own breeding attempts, is not restricted to members of the Picidae, but is shared with several other avian families; these are the parrots, the trogons (Trogonidae), the kingfishers, the jacamars and the puffbirds.

Compared with most of the Picidae, the Northern Flicker undertakes relatively little excavating work, and this may be the reason why it rather commonly chooses to breed in other, often peculiar, sites. Among these are not only fence posts, utility poles and nestboxes, which may be expected, but also such unusual sites as clothesline poles, marine breakwater pilings, cliffs of hardened silt or clay, haystacks, and a variety of suitable structures on buildings.

The small size of the piculets enables these diminutive woodpeckers to nest in a wide range of substrates. The holes of the Asian Speckled Piculet, for example, are generally located in small dead branches, in bamboo, or even in palm fronds. Slender stubs, branches and bamboo are also suitable nesting sites for the South American piculets and for the three African and Asian *Sasia* piculets.

Those woodpeckers which live in more or less treeless grasslands and which, in addition, have a bill that is of little use for hard woodworking must of necessity resort to ground burrows. One of the best examples is the Andean Flicker, which digs its tunnel-like nest into earth banks, among cliffs and in other rocky terrain; the tunnel is about a metre long, is horizontal or slightly upward-sloping, and ends in a nest-chamber. Only rarely does this species excavate in the *Polylepis* trees that are found in the Andean highlands. Its relative, the Campo Flicker, will either use nests of the arboreal termite *Constrictotermes cypergaster* or, in treeless country, dig into the mounds of a terrestrial termite, *Cornitermes cumulans*, or into earth banks. Like its South American equivalents, the Ground Woodpecker in South Africa digs its nest-tunnels into a bank, often in a road cutting, or into the ground among rocks.

The breeding cycle commences with the selection of a nest-cavity. Although woodpeckers are primary cavity-nesters, not all species construct a new hole each year. In particular, those woodpecker species which are not so well adapted for excavation often use old holes or, more rarely, nestboxes. Nevertheless, most

The Red-naped Sapsucker breeds in aspen (*Populus tremuloides*) and conifer forests of the Rocky Mountains, and spends the rest of the year in the high oak (*Quercus*) woodlands of the arid south-west United States and Mexico.

This woodpecker uses sap holes throughout the year, often exploiting pine (*Pinus*) trees in summer, as this male demonstrates. Each hole is cut so that the inner section holds a small quantity of sap. The holes sometimes merge into a vertical groove, into which the sapsucker places its bill and runs it upwards, sipping as it goes.

Sap wells created by sapsuckers are visited by various other picids, as well as other animals. Deer, squirrels, mice and a wide variety of insects take advantage of this free source of nutrition. Among the most frequent insects to exploit sapsucker wells are ants, which are, paradoxically, a major food of many picids.

of the other species, as typified by the American and Eurasian Three-toed Woodpeckers, practically always construct a new hole for each breeding attempt. Both the male and the female may advertise their individual roosting sites as the future nest-site, underlining their respective preferences by drumming in the vicinity of the prospective nest-site, performing display-flights and tapping at the hole. Both sexes may, in addition, begin to create one or several new holes. Later, activities are focused at one hole, which eventually becomes the male's roost and the pair's nest. Even so, the decision may still be revised immediately before egg-laying commences. It is the primary task of the male to construct a suitable hole and then to offer it as a nest-site.

Construction of the nest is an important ingredient of pair formation. The nest is not necessarily built completely anew in each breeding season, but some cleaning and other work at the hole is almost invariably carried out. The task of constructing a new hole from scratch takes a Black Woodpecker about two weeks if excavating in soft wood and up to four weeks in hard wood. Northern Flickers, if they breed in a tree cavity at all, spend from five days to three weeks in working at a hole. That species, as other picids less endowed with carpentering abilities, only infrequently excavates a completely new nest-hole, preferring instead to adapt a natural hollow or an old hole of another woodpecker if it cannot use the existing roost of the male. The Black Woodpecker, too, prefers to excavate holes in dead trees, which would seem to be due to the fact that less effort is required to dig into dead wood. Interestingly enough, this preference appears to be accompanied by certain costs, since the fledging rate has been found to be about 10% higher in nests that are constructed in live trees. In both of these species, which represent approximately the upper and lower ranges of excavating abilities among the true woodpeckers, the male takes the major share of the work of nest-construction, particularly in the final stage.

The first step in the construction of a hole consists in the excavating of the entrance part, which may be in hard, live wood. At this stage, the female and the male sometimes participate in equal share. After a deeper tunnel has been completed, and soft wood has been reached, the nest-chamber is dug out. This is usually pear-shaped or, in some cases, mainly involving small woodpeckers and piculets, rather cylindrical, and it follows closely the structure of the trunk or limb. The nest-chamber is created by forceful pecking and the tearing-off of pieces of the substrate.

Hammering is usually more rhythmic than that performed when foraging. Initially, all the work is carried out from outside the hole. In the final stage of construction, however, a bout of work typically commences with the woodpecker entering the hole and collecting wood chips. Beakfuls of these chips are then removed from the hole, the woodpecker sticking its head out of the entrance and characteristically tossing them away with energetic sideways flings. After chips have been removed, a task which

Woodpeckers drink frequently, this being especially so with those species which include pine (Pinus) seeds in their diet. Small puddles which form in tree forks, and in similar hollows in branches and trunks, are important sources of water for arboreal species. Tropical picids, such as the Hispaniolan Woodpecker, also take water that collects in the centre leaves of bromeliads, as well as using the plants as a source of insects. A female of this social woodpecker is shown here.

[*Melanerpes striatus*, Santo Domingo Botanical Garden, Dominican Republic. Photo: Doug Wechsler/VIREO]

Visiting a woodland pool, this Eurasian Green Woodpecker shows the method used by most birds, including the Picidae, to drink. Standing at the edge of the pool, its image perfectly reflected in the still water, into which it has inserted its bill to just below the surface, it tips back its head, allowing the liquid to flow down the gullet. Even the most arboreal species are sometimes forced to the ground to drink, from either temporary or permanent sources of water, if they are unable to find a suitable puddle in a depression in a tree.

[*Picus viridis viridis*, Heemskerk, The Netherlands. Photo: J. M. Lammertink]

Their intelligence and adaptability have facilitated the success of many woodpecker species. They regularly come to gardens for food and, as this male Golden-fronted Woodpecker demonstrates, will take advantage of any suitable human structure that provides a convenient source of fresh water. In its arid habitats in the southern United States and Central America, fruits and other foods, including insects, can supply a fair amount of the liquid requirements of this and other woodpecker species, but fresh water is also a necessity. Picids accept a wide variety of natural foods, often placed out specially to attract them, and many species are also avid consumers of highly nutritious suet. This provisioning may reduce the level of mortality during severe winter conditions in northern latitudes, enabling the birds to maintain their range farther north than would otherwise be possible. Tropical woodpeckers, however, are equally prepared to take advantage of the offerings of human beings, as can be witnessed by visitors to rainforest lodges across the world.

can take some time and is often the only activity at the nest immediately before egg-laying, some further excavation work may follow. Chip-tossing and a few occasional pecks can sometimes still be witnessed during incubation. The floor of the nest remains covered by wood chips, and these can later become soaked with the nestlings' faeces and form sticky clods, which are then removed by the parents.

Many trees provide a hard outer "shell" and a soft "heart", the latter caused by fungal heart-rot. A broken, cut or otherwise damaged branch may be the source of decay which continues in the limb or into the main trunk. Many holes are therefore sited immediately below such an injury. Tree fungi, such as the bracket-forming polypore *Fomes*, are also associated with soft heartwood, and woodpeckers frequently select spots just below these, the "umbrella" of the body of the fungus sheltering the hole entrance. The number of sites suitable for nest-excavation is limited, and it diminishes in accordance with a decreasing ability of individual species to construct a new hole in hard wood. Wood hardness decreases from live to dead trees, and with increasing height in trees. Given all the constraints associated with a good nest-site, nest-site availability plays a key role in the life of any woodpecker species (see also Status and Conservation).

Picid holes are often at the periphery of a home range and adjacent to a more open section of the habitat. In these circumstances, there is a need for the cavity entrance to be protected to a reasonable extent, and this is apparently achieved by means of its orientation. One study of hole-entrance orientation on artificial snags revealed that the entrances of holes constructed in the summer were randomly oriented, while those of holes made in the winter months faced away from the direction of the prevailing wind. Hole-entrance diameter depends primarily on the body size of the species in question, but it is also, to some extent, dependent on temperature. The colder the outside temperature is, the narrower is the entrance and the deeper is the chamber.

Many woodpecker species construct their holes on the underside of a sloping limb, and, furthermore, some holes are located even in virtually horizontal branches, with the entrance then facing vertically downwards. A good number of species excavate their holes in rotten stubs, an action which often weakens these stubs considerably. The result is that the pair loses its hole, because wind stress causes the wood to break at the site of the hole.

Hole-construction and nest-site selection are constrained by various ecological and, at least among co-operative breeders, demographic factors. This aspect has been particularly well studied for the Acorn Woodpecker. This species' preferred, or most commonly used, nest-sites do not necessarily coincide with those that are likely to produce the highest reproductive success. The woodpeckers show a clear preference for nesting in dead limbs, although nests in live wood offer a more favourable, less variable micro-climate. Nests excavated high up in trees and those in tree species with smooth bark provide the best protection from predators. Thus, the availability within a territory of large tree species, those that offer strong limbs even at great height, and of smooth-bark tree species has a restrictive influence on nest-site selection. The feasibility of digging a hole in live wood not only depends on species-specific morphological endowment, but is also constrained by the greater effort needed to carry out such a task. Large groups are more likely to be successful when engaging in such costly activities.

These findings probably apply to all woodpeckers. When Great Spotted Woodpeckers, for example, breed as low as a half-metre above the ground in a certain location, they do so almost certainly because no suitable large trees are available. The same is true also for other and larger species.

The peculiar nesting habits of the co-operatively breeding Red-capped Woodpecker illustrate the role of the nest-cavity in effective protection against predation. The male of this species selects holes according to the capacity of the respective pine trees to produce a good yield of resin. Roosting and nesting Red-capped Woodpeckers maintain a flow of resin around the hole entrance by daily bouts of excavating at small wounds, this fresh resin having the effect of preventing rat snakes (*Elaphe*) and nest competitors from entering the hole. With this species, incidentally, both male and female of the breeding pair, as well as helpers, take part in the construction of the nest.

Woodpeckers which dig their holes into live pine wood are obliged to make the nest-chamber only in the heartwood, where it cannot be filled by resin. Similar problems are encountered by those species which excavate live cacti, among which are several *Melanerpes* woodpeckers, the Gilded Flicker and even a few *Picoides* species. These are forced to wait until the sap dries up

Courtship displays of woodpeckers feature many elements that are used also when showing aggression. The crown feathers are erected, the head raised and the wings drooped. Mate-feeding has been observed as part of the courtship ritual of only a few picid species, among them two *Dinopium* species and two *Melanerpes*, but has only rarely been reported for the White-naped Woodpecker. Here, the red-crowned male of the latter has just presented his yellow-crowned mate with a beetle larva.

[*Chrysocolaptes festivus* festivus, Ranthambore, India. Photo: Don Roberson]

All woodpeckers raise their young in a hole of some type. In the majority of cases, this is excavated in a tree or branch.

The Great Slaty Woodpecker, at 50 cm long the largest Old World picid, typically nests high up, to 45 m, in the trunk of a large tree. Interestingly, this adult male, seen outside its nest-hole 28 m up in a very large, dying sal (*Shorea*) tree, was one of a group that included another male and a female, which together reared two young. This species' offspring often stay with the parents until a new breeding cycle begins; in this instance, a juvenile perhaps assisted with brood-rearing.

[*Mulleripicus pulverulentus* pulverulentus, East Kalimantan, Borneo. Photo: J. M. Lammertink]

While this male Golden-fronted Woodpecker has opted for a natural nest-site, many pairs of this species excavate cavities at the top of telegraph poles. Some poles can contain five or six nests and, in areas where this woodpecker is present in high densities, these can bring down telephone lines. In Texas, legal protection of the Golden-fronted Woodpecker was temporarily suspended in the twentieth century, such was the damage that its nests caused.

The majority of woodpecker species usually dig their holes either in rotten wood or in trees with a softwood core, since such sites are easier to excavate. Nevertheless, live timber offers several advantages, among them a less variable microclimate inside the hole, and better protection from potential predators, which find it more difficult to break into a hole in hard, live wood. The fledging rate among Black Woodpeckers (*Dryocopus martius*), for example, has been shown in some studies to be about 10% higher from nests in live wood than from those in rotten substrates.

before they are able to use the hole which they have created. The majority of woodpeckers, however, since they prefer to excavate the nest-chamber in the decayed softer parts of trees, do not face such problems.

In northern temperate zones, the breeding season for woodpeckers begins early in spring, with egg-laying occurring generally in April. In Europe, Black Woodpeckers sometimes commence laying in the middle of March, but most of this species' clutches are started in mid-April, which is also the time when Middle Spotted, Great Spotted and Eurasian Green Woodpeckers lay their first eggs. The Lesser Spotted Woodpecker begins slightly later, and the Grey-faced Woodpecker starts laying up to two weeks later. The Eurasian Three-toed Woodpecker breeds at higher elevations, and its egg-laying season is therefore delayed until the second half of May. Similarly, montane populations of the Great Spotted Woodpecker have a delayed breeding season compared with that of lowland populations, and their clutches are laid after those of the White-backed Woodpecker. In central Europe, the migratory Eurasian Wryneck, on its return from the African winter grounds (see Movements), starts to lay its eggs usually in the second half of May, although on rare occasions it may lay from the end of April. Besides this general pattern, actual laying dates may vary from year to year, as has been shown by U. Wiklander and his co-workers, who studied the population biology of the Lesser Spotted Woodpecker in Sweden over many years. They found that, as with many other bird species, the chances of survival of the fledged young decreased the later the laying date became.

Resource availability is certainly an important factor in determining the timing of the breeding season. In North America, late broods of the Black-backed Woodpecker, for instance, may be associated with forest fires, clutches having been initiated within a few days after the passage of a fire in the second half of June. Acorn Woodpeckers breed from April through to June, but they may also, rarely, nest in August and September. Not surprisingly, tropical species often breed at varying seasons, or throughout the entire year, depending on the locality and its particular ecological conditions. For woodpeckers, as well as other

avian species, which live in the tropics, clear associations between environmental conditions and the timing of breeding have still to be elucidated.

According to the information available, woodpeckers copulate relatively frequently. They often copulate near the nest when the latter is nearly completed, and during the egg-laying phase several copulations take place each day, sometimes separated by only short intervals of 15 minutes. Females often initiate copulation. A pattern typical of many, if not all, picids is the following: while the male is near or at the nesting cavity, generally engaged in excavation work, the female will fly first to the hole and then to a favoured copulation branch, where she adopts her soliciting crouch. An interesting phenomenon is the reversed mounting which forms part of the copulatory behaviour of some *Melanerpes* species, including the Red-bellied and Lewis's Woodpeckers, and which has also been recorded for the Middle Spotted Woodpecker. In this, the female begins the sequence and mounts the male, which then proceeds to perform the copulatory act proper in the normal fashion. Reversed mounting, which also occurs after a copulation, may be an exaggerated form of soliciting by the female.

Copulations by woodpeckers take place on more or less horizontal limbs, on which the female may perch lengthwise or crosswise. The usual procedure is that the female crouches down and the male mounts her; in the case of some species, this action by the male is associated with his fluttering or hovering above the female. The act of copulation lasts for six to 16 seconds, after which the male descends gradually and, usually, flies off; both partners commonly preen afterwards. Copulation is often introduced by some activity at the hole, especially tapping or mutual tapping (see Voice), and is generally accompanied by calls that are low in both pitch and loudness. Frequently, the same location is used in consecutive matings.

It is by no means uncommon for copulations to take place some weeks before egg-laying. They are often associated with disputes with intruders, and in these cases usually happen immediately after such a clash has occurred. Regular copulation reaches a peak during the period of egg-laying, and then peters out in the course of incubation.

The eggs of the members of this family are invariably white, like those of other hole-nesting species, although they can sometimes become stained by resin, or by other substances present in the nest. There are some differences in shape, some eggs being more spherical and others more elongate, and those of some species seem to have rather thin shells. Eggs are usually laid at daily intervals until the clutch is complete. Experiments have demonstrated that woodpeckers are indeterminate layers, which means that the number of eggs that a female will lay is essentially controlled by a predetermined clutch size, and not by the number of eggs that she has already laid during any particular breeding cycle. The removal of a new egg from a nest will, therefore, cause the female to continue to lay. When clutches have been experimentally manipulated in this manner, as many as 71 eggs have been obtained from a single female Northern Flicker, 28 from a Red-headed Woodpecker, and 62 from a Eurasian Wryneck.

Compared with most secondary hole-nesters, woodpeckers have relatively small clutches. Among the Picidae themselves, those species with a high propensity for nesting in old holes tend to lay larger clutches, while the clutches of tropical species are generally smaller. For example, the Eurasian Wryneck, which nests in pre-existing holes, lays seven to ten eggs, and occasionally as many as twelve, although a large percentage of its clutches contain a far lower number. In contrast, the tiny piculets of the tropics, from what little is known of their breeding biology, appear to have a normal clutch size of just two or three eggs. Furthermore, woodpeckers living in temperate zones exhibit some latitudinal variation in clutch size, which tends to increase with greater seasonality of the habitat: in other words, the greater the difference between biomass productivity in summer and that in winter, the greater the likelihood of more eggs being laid in each clutch. In the case of Lewis's Woodpecker, for instance, the average clutch size throughout its distribution in western North America is 5-8 eggs, with the number of eggs laid by each female ranging from five, or rarely four, to nine; most clutches, however, contain six or seven eggs, and the average number per clutch in-

Construction of arboreal nest-holes begins with a circular funnel, which is fashioned into a cylindrical hole to form the entrance. The entrance hole is generally narrower in cold climates than in the tropics, and, unsurprisingly, smaller species, such as the Olive Woodpecker, create smaller holes than do larger ones. Most woodpeckers take a couple of weeks to complete a nest-cavity, although they normally give up and find a new site if they do not find softwood beneath the surface. Many picids, in particular the smaller ones, excavate a nesting hole on the underside of a sloping limb, to protect the chamber from rain or melting snow.

In contrast to the Afrotropical picid in the preceding photograph, the Robust Woodpecker of South America is a very big picid.

Correspondingly, the entrance to its nesting cavity is significantly larger.

A hard outer "shell" and a soft inner core, in which the pear-shaped nest-chamber is excavated, are crucial to arboreal woodpeckers.

The birds probably identify trees having a soft "heart" by visual cues, such as damaged bark or the presence of fungal growth.

Since a broken or damaged branch allows the main trunk or limb to decay, holes are often sited below such an injury. Tree fungi are also associated with soft heartwood, as in this instance, where the pair of Robust Woodpeckers has excavated a large hole on a tree patterned by bracket fungi. The nest-hole of many woodpeckers is often at the edge of a home range, in more open habitat, its orientation providing some protection from the weather.

The entrances of holes constructed in winter usually face away from the direction of the prevailing wind, whereas those excavated in the warmer climate of summer are more randomly oriented.

[*Campephilus robustus*, Iguazú National Park, Misiones, Argentina. Photo: J. & A. Calo]

Dead wood is a key feature of the habitat of many woodpeckers, as it provides not only a source of invertebrates but also sites for nesting.

This male Greater Flameback has found an ideal location for its nest, in a tall dead tree.

This species can take up to a month to complete the construction of its nesting cavity, even with both sexes working in soft wood. As is the case with many medium-sized picids, the entrance is oval in shape and the chamber is not lined, although some of the last wood chips and flakes are usually allowed to remain on the nest-floor after excavation.

[*Chrysocolaptes lucidus guttacristatus*, Khao Yai National Park, Thailand.

Photo: C. B. Frith]

creases from south to north. Although nests with as few as three and even two eggs have been reported for this species, those clutches may well have been incomplete ones. Lewis's Woodpecker is, incidentally, the biggest of the *Melanerpes* species, and its clutch size, which is comparatively large for that of a picid, would seem to corroborate the suggestion that, among members of that genus at least, clutch size is correlated with body size.

Should a clutch be destroyed for any reason, the female will often lay a replacement. Otherwise, almost all woodpeckers for which sufficient information is available are generally single-brooded. Nevertheless, several *Melanerpes* species are known to be capable of rearing more than one brood in a season. The Gila Woodpecker, for example, not infrequently has two and even three broods in a season, and the Golden-fronted Woodpecker occasionally raises two broods in Texas and, rarely, up to three in Central America. Groups of Acorn Woodpeckers periodically have a second breeding season, laying in August and September, having already bred in spring; such second nestings tend to take place in years with good acorn yields and when breeding success in the preceding spring was poor. Other melanerpines which are occasionally multi-brooded include the Red-bellied Woodpecker and the Red-headed Woodpecker. Rare second broods have been recorded also for the Downy Woodpecker, the Red-cockaded Woodpecker and the Northern Flicker in America, and for the Black-rumped Flameback in the Indian Subcontinent. The Old World wrynecks, on the other hand, regularly rear more than one brood in a season. In the southern part of the Eurasian Wryneck's breeding range, about 20% of pairs start a second brood and a few attempt a third. Rufous-necked Wrynecks in Africa may be even more prolific, making up to four breeding attempts in a season; one pair successfully raised three successive broods, with periods of 14-24 days between the fledging of one brood and the laying of the next clutch.

Woodpeckers have rather short incubation periods, ranging from nine to 14 days. Incubation proper generally starts once the clutch has been completed, or a day or two before that, although brief bouts of nest attendance can sometimes be observed even before an egg has been laid. Both male and female parents have well-developed brood patches, and they share incubation duties. In the case of the Red-cockaded Woodpecker, helpers also develop small brood patches, and they, too, may incubate. The male sits on the eggs at night, and he also remains overnight in the hole with the young until the end of the nestling period. During

the day, the male and the female share incubation duties more or less equally, and no clear evidence has ever been obtained that would indicate an uneven average contribution of the sexes. During change-over, the individual arriving to take over duties sometimes announces its presence by tapping; otherwise, the partners remain silent, with only very low intimate calls sometimes audible if the two meet at close distance. This intersexual

The nesting and roosting cavities of the tiny, compact Grey-and-buff Woodpecker of South-east Asia are often close together. This male is one of four individuals of this species which roosted in adjacent holes in a dead tree, the toes of a female inside the uppermost hole being just visible. In this case, the woodpeckers are using holes made by a larger species of picid. It is not unusual among the members of this family for the male's roosting hole to become the nest-site of the pair, although that is unlikely to happen here, since the cavities are too large to be utilized by this species for breeding. Optimal nesting sites are used repeatedly by woodpeckers, often of several species, and more than one hole may be occupied at a time, especially in the tropics.

[*Hemicircus concretus sordidus*, West Kalimantan, Borneo. Photo: J. M. Lammerlink]

Several species of the genus *Celeus* regularly construct their nests in the huge tree nests of ants or, less frequently, termites.

The habit is particularly well known for the Rufous Woodpecker, the sole Old World representative of the genus. This species commonly excavates a breeding cavity in the football-sized nest of arboreal ants of the genus *Crematogaster*, as this one has done in Sri Lanka.

It is perfectly normal for the nest to be still occupied by the insects.

Quite how the birds protect themselves from the stinging ants is not known, but they may acquire the appropriate odour during their feeding visits. The ants, however, sometimes destroy the brood if the delicate balance is disturbed from outside.

FLPA]

behaviour has already begun in an earlier stage of the breeding cycle, during the period of hole-construction.

The eggs usually hatch within one and the same day, although there are occasions, as with the large Black Woodpecker, when hatching may be spread over two days. Unhatched eggs and dead nestlings are removed by the parents. Similarly, eggshells are often removed immediately, but they may also be left in the nest for several days. The chicks remain in the nest for a relatively long time, three to four weeks, which results in the combined incubation and nestling periods being similar in length to the total duration of chick development among other altricial birds of equivalent size. It has been suggested that the high fledging/incubation ratio of 2.09, compared with about 1.23 for other altricial birds, as well as the low embryonic metabolism of the Picidae, can possibly be explained by the problems of gas exchange in the nest-chamber.

As already mentioned (see Morphological Aspects), the chicks are completely naked when they hatch, and they do not develop any down feathers. They stick closely together, forming a pyramid, in order to keep warm, and are usually brooded by the parents during the first days of their life. The parents enter the nest to feed the chicks for the better half of the nestling period, only in the later stages provisioning them at the hole entrance. As a point of interest, the sex ratio of nestlings is balanced. Although there have been some estimates that have suggested otherwise, as, for example, in the cases of the Black Woodpecker and the Red-cockaded Woodpecker, these conclusions could not stand up to closer scrutiny and analysis when large samples were used.

Melanerpine and many other woodpeckers, including the wrynecks and piculets, carry food and deliver it to the chicks in the tip of the bill. Flickers, *Dryocopus* logcocks and *Picus* species, on the other hand, regurgitate the nestling food, which they carry in the oesophagus and proventriculus. These species which feed their young by regurgitation often bring in food to the brood

at longer intervals than do other picid species. In the earlier stages, both parents share the duties of brooding and feeding. Towards the end of the nestling period, however, one of the partners, generally the female, may drop out, and appear again later only to care for some of the fledglings. Only among multi-brooded species, mainly the melanerpine woodpeckers, does the female sometimes take over most of the chores at the end of the nestling period. This is possibly in order to free the male for the preparation of the next nest-cavity, so that the next brood can be initiated without too much delay.

During the first days, the parents have to encourage the young to open the bill in order to feed them. They trigger begging behaviour by touching the base of the chick's bill. Later, the scratching noises made by the adults when approaching the nest-hole, and the darkening of the nest entrance, are sufficient to elicit intense begging, which is also stimulated by the begging of a nestmate. Begging calls can often be heard emanating from the nest-site even when no parent is at the nest. At the end of the nestling period, the young are fed at the hole entrance, and it is by no means unusual at this time to see a single begging nestling peering out of the nest-hole and calling when the parents are away. The noise made by begging woodpeckers can be audible at great distances, but there are some species-specific differences. Eurasian Green Woodpecker nestlings, for instance, call more frequently and more loudly than do those of the Grey-faced Woodpecker, and a similar comparison applies to the Great Spotted Woodpecker and the Middle Spotted Woodpecker.

There appears to be great variation among pairs, and maybe even species, as to which sex contributes the more to nest sanitation. The nestlings produce their faeces soon after having been fed, and the faeces, often mixed with material from the nest-cavity floor, are then carried away by the adults. The nests of Great Spotted Woodpeckers and Acorn Woodpeckers, for instance, remain clean right up to the very end of the nestling pe-

In landscapes where trees are scarce, cactus stems provide a good substitute. In the desert areas of the southern United States and Mexico, several melanerpine woodpeckers regularly choose such sites for nesting, including the Gila Woodpecker. The pair shown here has built its nest in a giant saguaro cactus (*Carnegiea gigantea*), a typical nest-site of this species. Gilded Flickers (*Colaptes chrysoides*) also habitually construct their nests high up in a giant saguaro. Most picids rear only one brood in a single season, but the Gila Woodpecker often produces two or even three broods.

[*Melanerpes uropygialis uropygialis*, Saguaro National Park, Arizona, USA. Photo: François Gohier]

riod, whereas in those of the Golden-fronted, Grey-faced and Black Woodpeckers, among others, the parents, in particular the female, cease to remove excrement, debris and other extraneous material in the last days before the young leave the hole. Faeces are seemingly often collected from the floor of the cavity and are mixed with wood dust and chips. These hole contents are important in assisting nest sanitation for species such as the sapsuckers, which have rather liquid faeces with thin or, possibly, no faecal sacs. Helpers of the Red-cockaded Woodpecker contribute as much to nest sanitation, brooding and brood-feeding as do the two parents.

Observations have revealed that nestlings of the Black Woodpecker not uncommonly die of starvation even when there is no indication of any food shortage. This may suggest the existence of sibling competition, although there could also be other factors, such as diseases and parasites, that cause mortality of this kind. Older nestlings, at least, are rather aggressive towards each other. Woodpecker chicks also direct aggressive-looking actions towards the parents, which maintain an increasingly greater distance from the growing young when feeding them.

When disturbed in the nest, the young cease begging and crouch closely to the bottom of the cavity. Nestling wrynecks, if thus alarmed, exhibit a peculiar type of behaviour involving snake-like head movements and hissing. This reaction is fully developed in adult wrynecks which are threatened while in the hole: the hissing is then accompanied by crest-raising, and the head is moved slowly towards the intruder and then suddenly retracted. This unique behaviour has been interpreted as snake mimicry. Interestingly, wrynecks surprised in the open perform rather stereotyped head movements which, again, are rather reminiscent of those of a snake, although they do not normally utter hissing sounds in these circumstances.

Fledglings, having vacated the nest, are somewhat aggressive in their demands for food, uttering loud squeaking calls as they approach the parent. It is not unusual, especially among woodpeckers in temperate zones, for the two adults to divide the brood between them, the male accompanying one or more juveniles and the female the others. The period over which the juveniles are fed by their parents, or stay with them, is unknown for most species. Juveniles of the social Red-cockaded Woodpecker are fed for up to six months after leaving the nest. In the case of this and other eminently social picids, the young remain with the group for an extended period, possibly covering several years. Among several

tropical species, too, the parents accompany the young more or less regularly for a protracted period of time, and the family-members may remain together as a unit until the parents begin the next reproductive cycle. Some woodpeckers share their roost with a fledgling, in which case only one young is produced.

Nest success, calculated as the relative number of clutches which produce at least one young, is generally high among woodpeckers, typically from more than 70% to 100%, and this relates to the fact that these birds excavate their own nests. The majority of failures is due to the eggs not hatching or to the deaths of small nestlings. When Black Woodpecker chicks die, they do so mainly within the first ten days after hatching. In a 20-year study of the Black Woodpecker in central Germany, U. Lange investigated the breeding success of this species in an area dominated by coniferous forest, but with a deciduous element of about 10%. Of 238 broods, the success of 44 was not known; of the remaining 194 broods, however, he was able to confirm that 177, or 91%, were successful. The average productivity for all nests combined was 2.71, while the successful nests produced an average of 3.04 young each. Most failures were caused by the adults deserting the nest because of cold weather. Similarly, a ten-year study of Lesser Spotted Woodpeckers in southern Sweden revealed that the most common cause of breeding failure was the abandoning of the nest, although, in this case, this was precipitated by the disappearance of one of the adults. Altogether, 34% of the breeding attempts made by these small woodpeckers were without fledging success.

Sociality influences breeding success, too. In North America, studies of the Acorn Woodpecker have demonstrated that fledging success increases with group size. Similarly, Red-cockaded Woodpecker pairs with helpers fledge 1.5 times as many young as do unassisted pairs.

Although the range of potential nest predators of woodpeckers is limited, owing to the hole-nesting habits of these birds, predation at the nest is still an important factor in the nesting success of the members of this family. Predators are usually restricted by the size of the hole entrance. As a consequence, snakes, squirrels, martens (*Martes*), and other birds, including even other woodpeckers, are almost certainly the most significant nest predators. New holes excavated in live trees are least subject to predation. Holes in dead trees, or holes that are used repeatedly, run a higher risk of being preyed on. As mentioned above, Red-cockaded Woodpeckers carry out daily bouts of excavation at small

Terrestrial woodpeckers, such as the Ground Woodpecker, dig burrows for nesting purposes.

As an exposed vertical face is required for nesting, roadside verges are often used. The male Ground Woodpecker carries out the majority of the work of tunnel-excavation. When complete, the tunnel is about 1 m long, and at the end it contains an enlarged nest-chamber.

Pairs of this species, which is confined to southern Africa, will also occupy holes in a cliff face, and will even rear their young in a suitable hollow between rocks. It is not at all uncommon for a pair to use the same nest-site for a number of successive breeding seasons. Whereas the South American ground-dwelling picids, the Campo and Andean Flickers (*Colaptes campestris* and *C. rupicola*), are semi-colonial, the Ground Woodpecker is more of a solitary breeder, even though it is often seen in small groups.

Nevertheless, a helper, frequently a younger bird from the previous year's brood, often assists a breeding pair in providing food for the chicks.

wounds around the hole entrance, particularly around the lower rim, in order to maintain a flow of fresh resin, which generally prevents snakes from entering the hole. Even so, this may not be effective against other potential predators, nor against certain nest competitors such as southern flying squirrels (*Glaucomys volans*). Moreover, the mesh snake traps placed at the base of trees bearing cavities made by this threatened picid can sometimes have unfortunate consequences, when the woodpecker itself becomes ensnared and dies. There is also a documented instance of a Yellow-bellied Sapsucker being caught in such a trap, which resulted in its death.

Raptors, especially hawks (*Accipiter*) and buteos (*Buteo*), are known to prey on adult and, especially, juvenile woodpeckers outside the nest-hole or roost-hole. In North America, for example, there are numerous reports of Northern Flickers being taken by diurnal birds of prey, and it is likely that most picids are at least occasional victims of such avian predators.

The ability to construct holes as nest-sites is one of the key features of woodpeckers. Cavities provide almost perfect shelters for spending the night, as well as for rearing a family. It is hardly surprising, therefore, that holes made by woodpeckers have become a central resource for the survival of many other species of bird, as well as for many mammals, including bats, and other animals, even insects. Non-excavating avian cavity-nesters are often serious competitors for woodpecker nest-sites, and frequently force the rightful owners to leave a nest and to start excavation of a new one. In most parts of the world where the Picidae are represented, starlings (*Sturnidae*) are among the most persistent hole-usurpers, and in Central and South America tityras (*Tityra*) and some woodcreepers are equally unyielding. All of these bird species are notorious for the constant threat that they pose to woodpecker nests and roosts, but there are many others. Araçaris (*Pteroglossus*), for example, consume the eggs or chicks of the woodpecker before taking occupation of its hole. Hence, the nest, even if it is ready to be used, cannot be left unoccupied, and a prime task of the male is, therefore, nest defence. Only the immediate nest vicinity is defended from intruders.

In addition, African woodpeckers are regularly parasitized by honeyguides. Several members of the latter family, as part of their normal breeding strategy, lay their eggs in the holes of other birds. At least nine Afrotropical picids are known to suffer from

this nest parasitism. These are the Rufous-necked Wryneck, itself a secondary hole-nester, along with five or more *Campethera* species and three *Dendropicus* woodpeckers.

The many birds which rely partly or wholly on cavities made by woodpeckers include several ducks (*Anatidae*) and pigeons (*Columbidae*), parrots, owls (*Strigidae*), hornbills (*Bucerotidae*), certain crows and swifts (*Apodidae*), and a fair number of passerines, among them bluebirds (*Sialia*), tits and nuthatches. Indeed, the survival of parrot populations in some regions appears to be largely dependent on the existence of a healthy woodpecker population: for instance, in a study of four parrot species in an area of Atlantic rainforest in south-east Brazil, 36 of the 37 parrot nests found were in old picid holes.

During the construction or adaptation of a hole, most woodpeckers remain under immense pressure exerted by secondary hole-nesters and sympatric picid species. These may be little more than a minor nuisance, but they may also be formidable foes and incessant usurpers. In many areas, Common Starlings are the most important competitors for the holes of small woodpeckers (see Status and Conservation), although medium-sized picids are often able to cope with them rather successfully. Lewis's Woodpecker, for instance, appears to win most of its encounters with this widespread songbird, which has been deliberately or accidentally introduced not only in North America, where it has expanded considerably, but also in southern Africa and several other parts of the world outside its natural Eurasian range. A study of three species of woodpecker in Ohio, USA, in the early 1990's found that Red-bellied Woodpeckers lost 39% of their freshly excavated cavities to starlings; Northern Flickers and Red-headed Woodpeckers, however, were far more aggressive in defence, losing 14% and 15%, respectively, of their holes to the introduced starlings.

A most interesting account by A. Jha of the efforts made by another member of the starling family, the Jungle Myna (*Acridotheres fuscus*), to take over the hole of a pair of Black-rumped Flamebacks in a Calcutta garden, in east India, illustrates the aggression and persistence of these nest-usurpers. In mid-April, a woodpecker hole in a coconut tree (*Cocos nucifera*) was occupied by a pair of mynas, which had begun nest-building inside the cavity; the pair continued to collect material for a further three days, until, on the fourth day, a flameback was seen just inside the cavity entrance, having apparently taken over the

While a female Yellow-tufted Woodpecker investigates a snag, its mate makes the initial attempts at an entrance hole. Yellow-tufted Woodpeckers are communal breeders: a number of nests may be excavated in close proximity to each other in a single tree, with adults provisioning young in several of them. Co-operative breeding is most common among the members of this genus. Interestingly, a close relative of this species, the Yellow-fronted Woodpecker, has been filmed as the two members of a pair simultaneously built nest-cavities in a tree, the two holes separated from each other by no more than 40 cm.

[*Melanerpes cruentatus*, Tambopata-Candamo Reserve, Peru.  
Photo: Tui de Roy]

Building the nest is an important component of pair-bonding. For virtually all picids for which sufficient information is available, it is the male that undertakes the majority of the work.

This pair of Ashy Woodpeckers was watched during the early and middle stages of nest-excavation. Work was carried out daily, but only during the cooler morning hours, and the male did about three-quarters of the digging. The hole was 12 m up, and faced away from the direction of the strong morning sunlight; a few metres below it was another hole, this one shallow and incomplete, which had recently been abandoned by the pair.

It is rather common for members of this family to start several new holes, sometimes even completing more than one, before a final selection is made. The chosen cavity then becomes the pair's nest, and for the male, which always incubates at night, it also serves as a roost. Sometimes, at the last moment before the eggs are laid, a pair will even switch to another hole. Woodpeckers are generally monogamous, and incubation and the brooding and feeding of young are tasks shared by the two partners. A woodpecker is usually able to cope successfully with the work on its own only once the chicks are old enough for brooding to be no longer necessary.

Once they have made the initial funnel-shaped hole, small woodpeckers, such as this Red-headed Woodpecker of eastern North America, grip the lower rim of the entrance and forcefully peck and tear away pieces of wood, flicking them to the ground. Hammering is usually more rhythmic than when foraging. This barkless stump is a typical site for a Red-headed Woodpecker nest, the bird often starting the hole at an existing crack. This picid is one of several that face competition from other hole-nesting species, but it is vigorous in the defence of its hole, losing only 15% of its cavities to Common Starlings (*Sturnus vulgaris*).

[*Melanerpes erythrocephalus*, Alma, Marion County, Illinois, USA. Photos: Richard & Susan Day/Animals Animals]

hole. Over the following nine days, when the mynas repeatedly attempted to return to their nest, the woodpeckers chased them away and themselves entered the hole. Then, with no warning, a group of 25-30 noisy mynas appeared in the nearby trees; a few of them dashed inside the hole and forced out the incumbent flameback, while others attacked the woodpecker's mate perched outside on the trunk of the tree. In the ensuing fight, the mynas' ferocity was such that, to the observer, it seemed likely that they would kill the woodpeckers, but the intervention of a local boy caused all the birds to fly away. On the next day, the mynas were back in the hole, where they eventually reared two young. The flamebacks were not seen in the vicinity again.

Owls of many species frequently take over woodpecker holes, both old and new ones. Pygmy-owls (*Glaucidium*) make short work of the job, and can kill a woodpecker that is bold enough to resist the take-over of its hole.

From all this, it should be amply evident that woodpeckers, because of the part they play as hole-constructors in many habitats, and because of their important role in the food chain and in foraging actions, are truly keystone species in a great many of the earth's terrestrial ecosystems. This may be illustrated by an example from Peru, where a dead tree about 25 m tall was found to contain numerous woodpecker holes, six of which were simultaneously occupied by breeding birds; these comprised two pairs of *Aratinga* parakeets, one pair of *tityras*, one of *martins* (*Progne*), and two pairs of different woodpecker species, one a *Melanerpes* and the other a *Dryocopus*. There are many similar examples from all areas of the world range occupied by the Picidae.

Woodpeckers generally reach maturity in the first year of life. In many cases, they breed for the first time during the breeding season following the one in which they hatched. Members of co-operatively breeding species, however, may delay nesting themselves for several years, depending on when they obtain an opportunity to breed within the group.

For the majority of the Picidae, there is no information available on longevity or on average lifespan. Wrynecks generally live for two to ten years, while most picid species probably live for an average of two or three years. The maximum

age recorded for the Great Spotted Woodpecker is nine years, and that for the Northern Flicker is nine years and two months, while a Red-bellied Woodpecker has been known to live for twelve years and one month. A ringed Gila Woodpecker was recaptured when nearly eight years old, while American Three-toed and White-headed Woodpeckers live for at least six to eight years, and the same probably applies to the Black-backed Woodpecker and many other picids. The demography is well known only for the two best-studied social species. The Acorn Woodpecker may reach an age of at least 16 in the case of males and 15 in the case of females, and the Red-cockaded Woodpecker can live for at least twelve years. In the case of the former species, adult survival seems to be independent of age, but the sexes differ to the extent that male survivorship is positively correlated with group size.

Long-term ringing studies in Peninsular Malaysia have produced some interesting figures on the lifespan of a number of species, based on the intervals between retrapping of ringed individuals. For the Rufous Piculet, the longest interval was seven years and two months, while that for the Rufous Woodpecker was only three years. Among the Picini, the oldest Banded Woodpecker was one month short of six years, and two Laced Woodpeckers were still alive after nine years and ten years, respectively. In addition, of 35 Common Flamebacks, at least six survived for more than four years and at least three for over eight years; the oldest two were still alive after more than ten years. During these studies, a Buff-necked Woodpecker was retrapped when it had reached an age of five years and three months.

## Movements

For the most part, woodpeckers are sedentary birds. Only a very small proportion of species, or, rather, populations, can be described as truly migratory. Most of the movements undertaken by picids are dispersive, and involve mainly juvenile birds, and they are probably difficult to distinguish from seasonal shifts in habitat and altitude. Some species undergo eruptive movements that are driven by food shortage. Outbreaks of budworms and

similar pests, often associated with wind damage or fire, may attract certain woodpecker species from the local area, but rarely to the extent that the individuals involved travel any great distance to exploit such sources of abundant food. Most data on woodpecker movements, if they exist at all, are vague, and relevant information is either relatively scant or simply not available. The piculets, for example, are thought to be more or less completely sedentary birds. In Peninsular Malaysia, two ringed Rufous Piculets, both females, were retrapped after several years only about 800 m from where they had originally been ringed, but little else is known about the possible movements of these diminutive members of the family. In these circumstances, one cannot entirely rule out the possibility that at least some of them make local, seasonal movements.

Those woodpeckers that do migrate generally do so during the day, although these movements are seldom conspicuous and are, therefore, not well documented. Migrating woodpeckers do, however, sometimes form flocks, and it has been repeatedly noted that flocks of migrating Great Spotted Woodpeckers in north Europe also contain individuals of other picid species.

Dispersal and post-breeding nomadism are probably most pronounced among temperate species and also, possibly, among those species living in arid and semi-arid zones. In the case of tropical woodpeckers, the young, rather than dispersing from the natal territory, may stay with their parents for an extended period of time. Dispersal, or, rather, the reduced opportunities that it brings for acquiring a new breeding site, is one of the crucial aspects in the understanding of communal breeding by woodpeckers (see Breeding).

Observations of woodpeckers outside their normal breeding range are often the only indication of dispersal. For example, records of the Grey Woodpecker in west-central Mauritania, as well as in south Nigeria and coastal Ghana, are most likely to represent extreme cases of post-breeding dispersal. In Europe, the sedentary Middle Spotted Woodpecker appears intermittently outside its breeding range, as, for example, in Estonia, or in its former breeding area in southern Sweden, where its last successful nesting took place in 1980; indeed, individuals have even been seen at Sweden's famed coastal bird observatory of Falsterbo. The Eurasian Green Woodpecker, despite its signifi-

cantly larger size, exhibits juvenile dispersal mostly to distances of only 30 km, and rarely farther, although there are records of young birds moving up to about 200 km from the parental territory. One of that species' Asian congeners, the Lesser Yellownappe, may be a further example of a woodpecker dispersing to areas outside the normal breeding range, as it is known to reach north-east Pakistan on occasion, presumably from its nesting areas in the Himalayan foothills of north India. Although these are a few examples of longer movements made by woodpeckers that are generally more or less sedentary, dispersal can in some cases be over greater distances. The dispersive movements undertaken by juvenile Great Spotted Woodpeckers, for instance, regularly extend over 100 km, and can cover as much as about 600 km.

As stated above, it is often not at all easy to distinguish post-breeding dispersal from seasonal movements that are made in order to escape harsh climatic conditions. In the Northern Hemisphere, some of the occasionally more notable movements that are recorded for certain species, such as the Black Woodpecker, show a peak in autumn, but there seems to be no corresponding return movement in spring, although irregular movements may occur in the latter season as well (see also Status and Conservation). In comparison, altitudinal displacements show a much clearer pattern, generally, and such movements are rather widespread among picid species. In Asia, for example, northern populations of the Grey-capped Woodpecker move to adjacent lowlands in winter, and continental populations of the related Pygmy Woodpecker behave similarly. So, too, do Brown-fronted Woodpeckers (*Dendrocopos auriceps*), Himalayan Woodpeckers (*Dendrocopos himalayensis*) and Nepalese populations of the Rufous-bellied Woodpecker, all of which breed at high altitudes. Many other pied woodpecker species of the temperate zones of Europe and North America are known to be subject to varying degrees of altitudinal movement, descending to lower levels for the winter season. Even the largely tropical Arabian Woodpecker can be found down to the Tihama lowlands in the non-breeding, winter season, while at least part of the population breeding in the Asir Mountains moves upslope in the summer months. The colapline Dot-fronted Woodpecker, distributed at comparable latitudes in the Southern Hemisphere, in the Neotropics, also

The later stages of nest-building involve working inside the hole, which means that large quantities of wood chips and sawdust that collect on the floor of the nest-chamber have to be removed. This male Red-bellied Woodpecker, working inside an ash (*Fraxinus*) tree, brings wood shavings to the entrance hole and disposes of them in typical woodpecker fashion, with an energetic flick. Among many picids, copulation occurs during the period of nest-construction, reaching a peak just before and during egg-laying. The Red-bellied Woodpecker is, incidentally, one of several *Melanerpes* species in which reversed mounting has been observed, whereby the female mounts the male.

[*Melanerpes carolinus*, Cincinnati, Ohio.  
Photos: Dave Maslowski]

The way in which wood chips and flakes are removed from the inside of the nesting cavity during the process of construction is highly characteristic of the Picidae. The same method is employed by all species, from the smallest to the biggest. In these photographs, shards of wood are flung from the nest entrance by a male North American Pileated Woodpecker, one of the largest picids, and by a male White-spotted Woodpecker, a very much smaller member of the family living in South America. The technique of tossing out wood chips is essentially identical in both cases. The height at which the nest-hole is constructed varies considerably according to species. While the White-spotted Woodpecker tends to nest low down in a stub, the Pileated Woodpecker's nest is usually 6-12 m above the ground in an old tree and is sometimes as high as 30 m. Where huge rainforest trees are available, some of the larger woodpeckers nest at heights of up to 50 m.

[Above: *Dryocopus pileatus abieticola*, Rutland, Maine, USA. Photo: John E. Swedberg/Ardea.

Below: *Veniliornis spilogaster*, Iguazú National Park, Misiones, Argentina. Photo: Julián Alonso]

As with much else about their ecology and biology, relatively little is known about the breeding habits of the diminutive piculets.

The range of nesting opportunities is perhaps greater than that for larger woodpeckers, as very small trunks, branches and bamboo are all suitable sites. This White-wedged Piculet, however, has chosen a log that is in use as a fence post. From the little information available, a piculet's nest-chamber, which tends to be cylindrical rather than, as that of true woodpeckers, pear-shaped, typically contains just two or three eggs, fewer than the average clutch size of larger picids.

Mato Grosso, Brazil.  
Photos: Xavier Ferrer &  
A. de Sostoa]

moves a short distance downslope outside the breeding season, and the Chestnut-coloured Woodpecker wanders into Caribbean coastal scrub and mangrove during the austral winter.

A number of *Picus* woodpeckers in Europe and Asia exhibit similar altitudinal shifts on a seasonal basis. These include certain populations of the widely distributed Grey-faced Woodpecker, which move from breeding habitats at higher elevations to more favourable lower wintering grounds, such as riparian woodland and areas of human habitation. This is essentially true also for two of that species' congeners. These are the Scaly-bellied Woodpecker, the Himalayan populations of which partly descend to lower altitudes in winter, and the Japanese Woodpecker, which likewise moves to lower habitats in severe winters. A further example among the Picini tribe is that of the Bay Woodpecker, chiefly an upland breeder, which can be recorded at low elevations outside the breeding season.

Some species that occur in dry habitats also undertake seasonal movements. The Arabian Woodpecker has already been mentioned. Populations of Bennett's Woodpecker that nest in the most arid areas of this species' African range fly short distances to more moderate climates after the breeding season, and some seasonal movements appear to be made also by the White-fronted Woodpecker in the Neotropics. It is quite likely that similar short-distance flights are undertaken by other dryland woodpeckers.

As is to be expected, medium-range seasonal movements are most marked among woodpeckers living in cool temperate habitats. Some of the species involved may also migrate over larger distances. Many of these movements are irregular and nomadic and involve only certain populations, as typified by, for example, the Grey-faced Woodpecker. Apart from local altitudinal movements, this picid is basically as sedentary as most other members of the family, but members of northern populations wander variable distances in winter, and some Scandinavian individuals occasionally perform short migrations in autumn. In America, some Acorn Woodpeckers leave the breeding areas in autumn, and those of southern Arizona and the adjacent Mexican mountains possibly fly farther south in northern Mexico. The related Red-bellied Woodpecker concentrates in favourable areas in winter, and it may then occur outside its breeding areas, while the species' northern populations, at least in really harsh winters, migrate southwards. In the case of the congeneric Red-

headed Woodpecker, however, southward migration by northern and, especially, north-western populations is of more or less regular annual occurrence, and flocks of up to several hundred individuals can be seen during this passage in the period from August to November. In winter, these woodpeckers remain in regions south and east of a line drawn approximately from south Texas north to eastern Kansas and south-east Iowa and across to Ohio and New Jersey, returning to their breeding grounds in late February and March. Occasional Red-headed Woodpeckers are seen, in winter or summer, in areas west of the breeding range, even in western Canada and California, and there are also reports of this species flying over the Gulf of Mexico in October. The Green-barred, Striped and Chequered Woodpeckers serve as examples of medium-distance migrants from the Southern Hemisphere. In the case of the first of those three picids, at least some of the southernmost populations, after breeding in northern Patagonia, migrate to northern Argentina, as also do populations from the Cordoba highlands of north-central Argentina. Southern populations of the other two species migrate to, respectively, west-central Argentina and the Mato Grosso.

In the Northern Hemisphere, northern populations of the Lesser Spotted Woodpecker of Eurasia are at least partly migratory, and that species' Nearctic analogue, the Downy Woodpecker, may also be so. In the case of the former, north European birds sometimes reach the Black Sea; the migration is often irruptive and may parallel the more striking movements of Great Spotted Woodpeckers. Although even northern and montane populations of the Downy Woodpecker have been found to be residents for the most part, a degree of movement has been observed along the Atlantic coast which could indicate that, locally, this woodpecker may be partially migratory; furthermore, in the west, some individuals have been known to reach Mexico. It has been suggested, however, that these movements, rather than representing true migration, involve dispersing individuals.

While northernmost populations of the New World Hairy Woodpecker show some unspectacular seasonal movements, those of the similarly sized Great Spotted Woodpecker in the Old World are subject to eruptive and conspicuous migrations. These periodic exoduses are triggered by poor crops of pine or spruce seeds, and they begin in late summer, after the breeding season; individuals may stray more than 3000 km, and some ar-

rive on islands, even remote ones. Although this phenomenon occurs occasionally among this species' Far Eastern populations, it is considerably more striking in Europe, where mass emigration from Scandinavia and Russia can involve many thousands of woodpeckers. For example, in a massive eruption that took place in the autumn of 1962, numbers of Great Spotted Woodpeckers on the small south Finnish island of Sääpi, in the Gulf of Bothnia, reached a peak of about 10,000 on 17th August; more recently, 2240 passed through a single site in Latvia in autumn 1999. An interesting aspect of these periodic large-scale movements, which are comprised chiefly of juveniles, is that other picids are often caught up in them. In this context, allusion has already been made to the Grey-faced and Lesser Spotted Woodpeckers, but another species deserving of mention in this regard is the White-backed Woodpecker. Some local movements aside, this attractive pied woodpecker is chiefly a resident, but its continental populations occasionally undertake eruptive southward or westward migration, sometimes in connection with similar movements by Great Spotted Woodpeckers, and relatively large numbers from Russia can then reach Finland and Sweden.

The two three-toed woodpeckers of the Holarctic Region perform eruptive migrations as well. Although mountain populations of the Eurasian species are largely sedentary, those breeding in the northern parts of the range rather frequently move south and west after breeding, sometimes in reasonably large numbers, and the Siberian subspecies *crissoleucus* regularly migrates greater distances. In eastern North America, American Three-toed Woodpeckers move south at irregular intervals, and a similar pattern of periodic migration is followed by the closely related Black-backed Woodpecker. These eruptive movements, while certainly not approaching the proportions of those exhibited by *Picoides* species in northern Europe, can at times be notable. The largest invasion of Black-backed Woodpeckers in the north-eastern USA occurred in 1974, when over 460 individuals were estimated to have arrived from their breeding areas in the boreal forest of eastern Canada. It is thought that these irregular eruptive migrations may be caused by regional population increases brought about by very favourable conditions, such as outbreaks of spruce budworm, or, conversely, they may be precipitated by a lack of suitable food in the form of wood-boring insects.

The annual movements of Lewis's Woodpeckers, which travel variable distances after breeding, do not always involve all the individuals of a population. Of particular interest, however, is that the change from living in open pine woodland during the spring and summer breeding season to spending the rest of the year in oak woodland and orchards is associated with significant changes in the diet. From being an insectivore during the breeding period, this North American woodpecker becomes a vegetarian in autumn and winter, when it feeds mainly on acorns or nuts, supplemented by fruits. In August and early September, Lewis's Woodpeckers are largely nomadic, wandering to other habitats in the mountains or visiting orchards. At this time they move around in flocks and, if suitable winter habitats are very close by, they need to travel only small distances. Only about half of the population in south-eastern Colorado leaves the breeding area, whereas the populations of Idaho, Wyoming and Montana are probably forced to migrate longer distances. The winter range is generally within the southern portions of the breeding range, northwards to Oregon and, in smaller numbers, to British Columbia, but in the south some extend outside the breeding area to as far as north-west Baja California, eastern Arizona and southern New Mexico, and, rarely, into northern Mexico. Climatic conditions and the distribution of acorn crops largely determine the winter distribution. This species' migrations can on occasion be rather spectacular, with totals of up to 2000 or more birds, in flocks ranging from two or three individuals to several tens, passing a particular place in one hour. Food supply is the most important criterion for Lewis's Woodpecker when it comes to selecting the wintering habitat, and that is why oak woodland, commercial orchards, especially of almond (*Prunus amygdalus*), walnut (*Juglans*) or hickory, and other areas with ample food supply, such as corn, are preferred.

Those populations of the Northern Flicker that breed north of a theoretical line joining the northern parts of California, Oklahoma and Virginia are migratory, although there seems to be some difference in this respect between the red-shafted form in the west and the eastern, yellow-shafted flickers. The former is certainly migratory in Alaska and western Canada, but it may be less inclined to move far from the breeding areas in its western USA range. Unlike Lewis's Woodpecker, which migrates mostly by day, flickers are chiefly nocturnal migrants. Nevertheless, they can be seen migrating during the day, too, in sometimes large flocks, flying low over the ground. Their wintering grounds are concentrated in the USA, from the south-western states through Texas to Florida, with a few extending south into northern Mexico.

In the New World, the most migratory of all the woodpeckers is the Yellow-bellied Sapsucker, which winters far south of its breeding range in Canada, the north-eastern USA and the Appalachian Mountains. This melanerpine species ranges in winter from about south Kansas, southern Ohio and Connecticut southwards through Texas and the Gulf Coast states to Mexico, and beyond through Central America to Costa Rica and, rarely, to Panama. The entire West Indies are also included in the species' winter distribution, which covers a wide variety of habitats ranging from forest and forest edge, and various semi-open habitats, pastures and clearings, to orchards and even suburban areas, as well as coastal palm groves. The Red-naped Sapsucker, confined to western North America, is less migratory than its relative, and winters from Arizona south to north-west Mexico, although a few may occasionally reach the northern parts of Central America. Its non-breeding habitats in Arizona are oak woodlands mixed with juniper (*Juniperus*) or pine, or pure oak woodland, in upland areas, whereas it normally shuns oak and pine woodland when breeding. The Red-breasted Sapsucker, breeding along the North American Pacific coast, is even less migratory than the last species, even its northern, nominate subspecies being virtually sedentary. Some do leave the breeding grounds, however, and the species winters south to northern Baja California. The fourth sapsucker, Williamson's, is almost restricted as a breeding bird to the western half of the USA, extending only a short way north into Canada and south into the Mexican mountains. It is a partial migrant, and it appears that western populations do not move so far as the eastern ones, which

With less need for camouflage against passing predators, the eggs of woodpeckers are invariably white, making them easier for the parents to see within the dark nest-chamber. Nests are unlined, apart from a bed of remaining wood chips. These are especially important in nests such as this Yellow-bellied Sapsucker's; as the liquid nestling diet results in thin or non-existent faecal sacs, droppings are mixed with the chips to facilitate their removal by the parents. The number of eggs laid is determined by optimal clutch size, not by the number already laid. A female Northern Flicker (*Colaptes auratus*), when her eggs were experimentally removed, continued to lay, and produced 71 eggs.

[*Sphyrapicus varius*, Ontario, Canada. Photo: George Peck]

Incubation, which begins within a day or two of the clutch being completed, is short, but the young stay in the nest for a relatively long time and, in some cases, remain with the parents for months after fledging. Although the male sleeps in the nest at night, incubation and brooding during the daytime are usually shared by the parents, which work in shifts.

A male West Indian Woodpecker is pictured here outside the nest as his mate is about to leave; change-over is accompanied by low calls.

With this species, the male does most of the brood-feeding, enabling the female to regain condition for a second clutch, which is not uncommon for this picid.

VIREO]

migrate down into Sinaloa and Durango, some even reaching as far south as Michoacán in southern Mexico. Again, this woodpecker, which breeds in coniferous forest, has somewhat different preferences in the non-breeding period, which it spends in humid to mesic habitats such as pine-oak and oak-juniper woodland. Various observations indicate that, for all four sapsucker species, the females winter farther south, and the males return to the breeding grounds earlier than do the females.

The migratory capacities of the Yellow-bellied Sapsucker are reflected in the fact that it has been recorded on at least three occasions in western Europe. There are also three records of the Northern Flicker in Europe, but in this case considerable doubt surrounds the provenance of the birds: two were almost certainly "ship-assisted" and had hitched a ride on an ocean-going vessel, while the third, a corpse, is presumed to have died while on a ship at sea.

Notwithstanding the migratory feats of some of the North American picids, it is in the Old World that the most spectacular examples of migration by woodpeckers are found. The isolated north-east Asian population of the Rufous-bellied Woodpecker in Manchuria and Ussuriland seems to be totally migratory, the birds passing through central China in autumn and spring as they commute to and from their wintering grounds in southern China. While it could be argued that this journey is rivalled by that made by some of the sapsuckers in North America, the same cannot be said about the migration of the Eurasian Wryneck. This aberrant woodpecker is a genuine long-distance migrant, making annual southward flights of 8000 km and more to its non-breeding quarters, and capable of covering a distance of over 600 km in eight days. In contrast to the true woodpeckers in the subfamily Picinae, wrynecks migrate mainly at night. All northern populations in the huge range of the species are summer visitors to those regions. The European and west Asian populations winter in the savannas and drier areas of West and Central Africa, while those breeding in eastern Asia migrate to the Indian Subcontinent and South-east Asia. Some individuals of the nominate form winter in Mediterranean countries and in south-east Iran. The less migratory wrynecks breeding in the Mediterranean region and north Africa migrate only short distances or move altitudinally. In autumn, European breeders cross the Alps in August and Septem-

ber and then move down through the Iberian Peninsula or the Balkans; every year at this season, some Eurasian Wrynecks from Scandinavia migrate through Britain, where they can be especially numerous during anticyclonic conditions, when they are drifted westwards by easterly winds. At least a proportion of those populations breeding in the western half of Asia probably fly over Turkey and the Arabian Peninsula. The relatively clumsy wrynecks sometimes pay a heavy toll to Eleonora's Falcons (*Falco eleonora*), which specialize in capturing tired migrant birds as they attempt to cross the Mediterranean Sea. Many Eurasian Wrynecks do not leave Africa until April, arriving back on the breeding grounds in May.

Fewer details are known about this species' movements in eastern Asia, where migrants are recorded in Korea in September and in April and May, and occasional individuals turn up in western Alaska, but the general timing appears to parallel that observed in the western parts of the range. In Japan, wrynecks breeding on Hokkaido leave in August and September and return in late April and May; although a few appear to spend the non-breeding season in the southern part of the country, southwards from central Honshu, the great majority leave Japan after breeding.

The Eurasian Wryneck's African sibling species, the Rufous-necked Wryneck, is partially migratory in the southern parts of its range. Some individuals, after having bred in South Africa, move as far north as eastern Zaire, and migrants are recorded in February and March as they pass through north-eastern South Africa.

### Relationship with Man

Probably the majority of people are able to recognize a woodpecker as such, although many non-naturalists might not be aware that the wrynecks and the piculets are also woodpeckers. With their frequently colourful plumage, their habit of tapping and drumming on wood and other surfaces, and their close association with dark cavities, the woodpeckers have long been a source of intrigue for humans. References to these fascinating and often beautiful birds can be found in legends and creeds dating right back to ancient civilizations. It is only in the African continent that this

Without a specialist bill to excavate wood, some picids depend on existing cavities for nesting. These species tend to lay larger clutches: seven eggs is not atypical for the Eurasian Wryneck, and some individuals can lay as many as twelve eggs in a single clutch. Feeding so large a brood requires dozens of foraging trips each day, both parents carrying in food and removing faeces for three weeks, at which time the young wrynecks leave the nest. Those species which excavate their own holes, the majority of the Picidae, produce smaller clutches, probably because they are not limited by the availability of nest-sites, and therefore require less reproductive effort during their lifetime. Even these, however, need to make frequent feeding visits to satisfy the demands of their young.

Oxford Scientific Films]

avian family appears to have had little influence on humans, but that may be because woodpeckers are, on the whole, less numerous there than they are elsewhere in their world range.

Generally, the true woodpeckers of the Picinae tribe are rather popular birds. In most parts of the world where they occur, they are welcomed as attractive and interesting creatures which enliven the local forest, woodland or gardens. A very large number of these species, representing virtually all genera, have also been kept in captivity, and many have been bred and reared successfully. Great Spotted Woodpeckers are a prime example of this, but numerous others, including lesser-known picids such as the Asian Fulvous-breasted and Black-headed Woodpeckers (*Picus erythropygius*), have been kept in aviaries.

Woodpeckers have been used as recognizable symbols in advertising, although it is difficult to find any relationship between a pecking and digging picid and an alcoholic beverage. Perhaps a clue is to be found in one of the many humorous folklore tales recounted in the Canadian province of Manitoba. The story, although not meant to be taken seriously, tells how the Yellow-bellied Sapsucker missed the official "handing-out of colours" to birds because, through constantly drinking the sap of birch trees, it had become too inebriated to attend the ceremony; the other birds, having received theirs, presented the sapsucker with a variety of colours in order to console it.

In North America, a famous cartoon feature has "Woody Woodpecker" as its main character. The bird's laughing voice is intended to represent its song, and one can, with a little imagination, accept this interpretation. On the other hand, the cartoon woodpecker's lightning-rapid drilling to create a hole, and the combination of this action with powerful bill blows, are departures from the reality of the genuine picid's behaviour, even if such fanciful ideas appeal to the viewing audience.

Woodpeckers are mentioned in poetry, too. One of the best examples is provided by the seventeenth-century poet Marvell, in which the description of the foraging behaviour of the "Hewel", a derivative of the Anglo-Saxon *hyghwhele*, the name used for

the Eurasian Green Woodpecker, demonstrates the poet's joy in accurate observation of nature:

"He walks still upright from the Root,  
Meas'ring the Timber with his Foot;  
And all the way, to keep it clean,  
Doth from the Bark the Wood-moths glean."

Another superb example, this time referring to the varied diet of the Northern Flicker at garden feeders and in fields, comes from the pen of G. Newkirk, a dentist and poet who lived in California in the latter part of the nineteenth century. Newkirks's anthropomorphic verse gives voice to the flicker:

"And I like dessert in reason,  
Just a bit of fruit in season,  
But my delicacy is ants,  
Stump or hill inhabitants;  
Thrusting in my sticky tongue,  
So I take them, old and young."

The striking vocalizations of many picids have earned them a myriad of colloquial names. In Britain, for example, the Eurasian Green Woodpecker's laughing call is reflected in countless local names, one of which, "Yaffle", is still used today by some countryfolk. By the end of the eighteenth century, this name, which may possibly have descended from Anglo-Saxon, had become the usual one for the species, and its meaning was even extended to denote the making of a woodpecker-like sound by a human. In parts of France, this species is known as "the miller's solicitor", because it announces the imminent arrival of rain and the consequent rising of water levels that will allow the mills to work. Indeed, the name "Rainbird" was applied to the Eurasian Green Woodpecker in many European languages, as in the German "*Regenvogel*", and it was similarly used for the Eurasian Wryneck, also said to be a predictor of rain. Another old German

On returning to the nest with food, woodpeckers rarely fly directly to the entrance hole. Most alight on the substrate a few centimetres to the side, or sometimes above, the entrance. Here, the male Red-necked Woodpecker takes a few seconds to check that there are no predators, either inside the cavity or on a nearby branch. He can also establish, through quiet calls, whether his partner is already attending the chicks. Once convinced that all is normal, the bird will move quickly to the entrance hole and drop inside. As the chicks develop and fill the nest-cavity, the adults bring food only to the entrance, as the Little Woodpecker in the lower photograph is doing. Prey fed to the brood increases in size as the nestlings grow.

In addition, and not surprisingly, it varies in proportion to the size of the bird, as is obvious from the differences in size of the larvae being delivered by these two Neotropical species.

name for the wryneck, once a very common bird in the European countryside, was "*Gießvogel*", after the word *Gießen*, meaning teeming rain, but also, coincidentally, reflecting that species' song, "giaß, giaß,...". In America, early colonists from Europe invented all kinds of names for the birds that were new to them, in many cases referring to what were, to the settlers, unusual vocalizations, colours or patterns, or aspects of behaviour.

Myths and legends surrounding woodpeckers date far back in history. In the legend of Romulus and Remus, the twins who founded the city of Rome, the woodpecker, besides helping the wolf to feed the twins, also helped it to defend sacred trees. A Roman coin shows the wolf feeding the two foundlings beneath a sacred fig (*Ficus*) tree in which two woodpeckers are perched. For the Romans, the woodpeckers held a place of particular honour, and were considered to represent industry, bravery and war. The association between the woodpecker and Mars, the God of War, is a very old one, and the connection can still be seen in the scientific name of the Black Woodpecker, *martius*. It is also of interest to note that, before the systematic scientific naming of animals and plants came into force, the name "*Picus martius*" was applied to other species, in particular the Eurasian Green Woodpecker.

The woodpecker features also in Greek and Hindu mythology and legends. Like the greatest of the Greek gods, Zeus, the Hindu God Indra was said to transform himself into a woodpecker in order to pursue his amorous adventures. In Europe, a Black Woodpecker's feather was regarded as making the person who held it lucky in love.

While superstitious beliefs ascribe the ability to forecast the weather to several kinds of bird, foremost among these are the woodpeckers. Notions of woodpeckers as rain-forecasters are widespread in many parts of the world. The Guadeloupe

Woodpecker's drumming was thought by some to foretell the arrival of rain. In many European countries, the call of the Eurasian Green Woodpecker, when slow, drawn out and doleful, was said to announce the imminent arrival of rain. Ancient European peoples believed that this bird was a prophet, especially of rain and storms, and that it had supernatural powers because of its association with thunder, rain and fertility. E. A. Armstrong, after examining all the various myths and legends, and the clues contained within them, concluded that a "woodpecker cult" existed in Neolithic times, when oak forest still covered extensive areas of Europe and, at the same time, humans were starting to cultivate the land. Rain is of great importance for cultivation, and the woodpecker bringing the rain would also symbolize fertility. The bright green colours of the Eurasian Green Woodpecker, and its habit of digging into the ground, would have served only to reinforce such beliefs; moreover, it has even been regarded as having inspired the invention of the plough. This species was a rain-forecaster to the druids of ancient Britain, to whom the oak tree was sacred. The woodpecker's association with oaks would naturally have led to its being regarded as having special powers.

When theistic religions and Christianity came more to the fore, a switch in emphasis appears to have taken place. The woodpecker had, it seems, acquired too high a position in life and needed to be "put in its place". This is revealed by a number of interesting tales and legends in which the woodpecker is punished for its disobedience. One story, from the Gironde region of south-western France, relates that God, after having created the earth, ordered all the birds to excavate the hollows that were destined to become seas and wetlands; the woodpecker was the only one to disobey. Later, when all the other birds had completed the work, God decreed that the woodpecker, since he had

Woodpeckers which obtain most of their food by gleaning bring a greater number of prey items to the nest in each delivery than do those which peck and hammer for food. This female Grey-capped Woodpecker is returning to her nest, in eastern Siberia, with the bill stuffed full of invertebrates. The food delivery also includes a small snail, which should provide the nestlings with a challenge. The diet of young picids is usually made up of easily digested soft-bodied insects, and includes less plant material than that of the adults.

[*Dendrocopos canicapillus doerriesi*, north Ussuriland, south-east Siberia, Russia.  
Photo: Yuri Shibnev]

At least 60% of all woodpecker species include ants in the diet, but the two wrynecks which constitute the subfamily Jyninae are true ant specialists. Because ants occur in great quantity in concentrated sources, these picids are able to collect the food and deliver it to the young in bulk. This is perfectly illustrated by this Rufous-necked Wryneck, which has returned to its nest-hole with a massive load of ant pupae for its chicks. Adult wrynecks feed both themselves and their nestlings on ants, including their pupae and eggs, obtained from terrestrial nests by gleaning and probing. They exploit ants of many different genera, using the sticky tongue which, unlike that of other picids, is smooth and barbless. Mate-feeding forms part of the courtship ritual of the wrynecks, and the male sometimes continues to feed his partner even during incubation.

Woodpecker chicks hatch naked and blind. All brood-members usually hatch on the same day, and develop to fledging over the relatively long period of three to four weeks in the nest-cavity.

At this very early stage, when just a couple of days old, these six young Northern Flickers respond to the returning female with urgent begging calls. Woodpeckers deliver food to their nestlings by one of two methods. Either they regurgitate it, as is the case with the flickers and two other genera, or they pass the food from the bill tip to the chick's mouth, a technique employed by the wrynecks, the piculets and many of the true woodpeckers. Visible on some of these nestlings are the pads at the base of the lower jaw, which extend over the edge of the bill. These assist the parents in the transfer of food in the darkness of the hole, and they will have disappeared almost completely by the time the chicks fledge. The clutch size of Northern Flickers varies considerably, both with timing of laying and with latitude. Clutches laid earlier in the season tend to be larger than later ones, and clutch size increases gradually from south to north. The latitudinal increase is of the order of one egg for every additional 10 degrees of latitude.

[*Colaptes auratus luteus*, near Dexter, Maine, USA. Photo: Dwight R. Kuhn/DRK]

With still at least a week until their first flight, these young Pileated Woodpeckers can only lie in their natal cavity, waiting for food, and for their juvenile feathers to develop. Thin sheaths remain on the flight-feathers, although the red crown is already obvious. The coloration of some young woodpeckers differs strikingly from that of the adults, with juveniles of several species showing markings that are lost after the first moult. Young Great Spotted Woodpeckers (*Dendrocopos major*), for example, possess a red forecrown, whereas this part of the plumage is black on the adults of both sexes.

[*Dryocopus pileatus abieticola*, near Harrisburg, Pennsylvania, USA. Photo: Joe McDonald/DRK]

been unwilling to peck at the ground, would for the rest eternity be assigned to pecking at wood, and, as he had refused to assist in the digging work, he should drink nothing but rain. That is why he is always calling "pluie pluie", the French word for rain, and always climbing upwards in order to obtain the drops falling from the sky. This tale would seem somewhat ironic if it were intended to refer to the ground-digging Eurasian Green Woodpecker, the most visible and widespread picid in the region; it would apply better to the Black Woodpecker, although that species was not present in south-west France until relatively recently.

An Estonian version of the story appears to relate more obviously to the Black Woodpecker. In this, the woodpecker refused to help in the digging because he did not wish to get his fine golden coat dirty. His vanity earned him severe punishment from the Lord, who stated that the woodpecker would henceforth wear a cloak of sooty-black and would be able to drink only from rain falling from the sky; his voice would be heard only when all the other birds were seeking shelter from approaching storms.

Other stories tell of the woodpecker's lack of charity. In Norse legend, the Lord and St Peter, hungry after having walked far, called upon a woman named Gertrude, who was baking cakes and wore a close-fitting red cap on her head. When they begged her for food, her baking efforts all produced cakes that were, she said, too big; she was unable to provide any that were small enough to be given away, so she told the visitors that they must go without. The Lord replied that, since she had so little love as to begrudge the hungry travellers a morsel of food, she was to be punished by being turned into a bird that seeks food between bark and bole and never gets a drop to drink. She was immediately transformed into a woodpecker, and flew straight up the chimney. The legend says that "Gertrude's bird" can still be seen flying around, with her red cap on her head and her body all black from the soot of the chimney. This is clearly a reference to the Black Woodpecker.

A variation of the same Scandinavian legend was given by a French priest. In this, Gertrude made her husband's life a misery, and the wretched man said that he would not go to paradise if his wife went there. One day, a poor man came to the door and asked for water, but Gertrude pushed him away with threats and abuse; the caller was Jesus Christ. Because Gertrude would not give to the poor, she was sentenced to a life of eternal wandering and insatiable thirst; furthermore, for the whole universe to know

her and her sinfulness, she would always wear a red beret on her head and would announce, with a plaintive call, the water that she would seek in a vain quest to satisfy her thirst. Gertrude was instantly transformed into a woodpecker; in this version of the story, however, she becomes a green woodpecker.

The use of woodpecker feathers in ornamentation appears not to be very common. In western North America, the finery of the Klamath Indian shamans included tiaras made of the skin of Red-headed Woodpeckers, and necklaces made of golden woodpecker feathers. The Pomo Indians of California fashioned exquisite coiled baskets studded with crests of quails (*Lophortyx*), the scalps of various woodpeckers, and hummingbird feathers. They used the red feathers of the Pileated Woodpecker primarily for currency, and only to a very limited extent for ornamentation. It seems, however, that the Acorn Woodpecker, which was abundant in California, was more heavily exploited there, and probably elsewhere in the western USA and Mexico, for its brilliant red head feathers. One full-size cape was found to be covered all over with the red crown feathers of this species, and it has been suggested that several thousand individuals may perhaps have been killed to decorate this single garment. The woodpeckers were often trapped as they emerged from the overnight roosting holes.

The same native Indians also used Acorn Woodpeckers for food, although picids in general appear not to have been utilized to any great extent for this purpose. The fact that they have a relatively tough skin and emit a strong, resinous odour (see Morphological Aspects) may have something to do with this. In the nineteenth century, European settlers in North America, as well as using flicker feathers to decorate hats, sometimes sold these woodpeckers in food markets; the roasted birds were thought by some to taste like ants, a major food of flickers. During that same period, the flesh of the Red-headed Woodpecker was described as being tough and having a strong smell of ants and other insects, which rendered it barely edible. Interestingly, the Tuaguses, a nomadic tribe inhabiting a region of the upper Yenisey, in central Siberia, believed that the flesh of the Grey-faced Woodpecker possessed special powers. The flesh was roasted, ground up and mixed with fat, and the mixture was then applied to the tribe's hunting arrows. It was claimed that any animal hit by one of these coated arrows always died.

As the chicks become older, the most robust nestlings scramble to the entrance hole, often by stretching across the nest-cavity, testing their strong toes on its opposite walls. This nestling Bennett's Woodpecker has just been fed at the nest entrance by the female parent. The chick can be identified as a male by its black malar stripe. Young females, incidentally, generally show at least some indication of the brown ear-coverts and brown chin and throat which distinguish the adult female from the male. The Bennett's Woodpecker, patchily distributed in southern Africa, where it prefers open miombo (*Brachystegia*) woodland, is an interesting picid. Outside the breeding season it is rather social, often being seen in small groups, which spend most of the time foraging on the ground in grassy areas. These parties frequently accompany glossy starlings (*Lamprolornis*) as they search for ants and termites and their nests.

Many woodpeckers frequent the tops of trees, at least at times, and so they are close to the sun. Because of this, the bright red and yellow feathers of some species have been thought to be associated with the origin of light, the sun, and with fire. Various native peoples in America, including the Klikitat of Washington, in north-west USA, and nearby tribes in British Columbia, believed that the woodpecker was the master of fire. One of the stories of the Kutenai tribe tells how Coyote, the son-in-law of Sun, in order to assure successful hunting, traversed the savanna while wearing woodpecker feathers tied to his moccasins, lighting fires wherever he ran. In Asia, there is a similar connection between woodpeckers and fire in Malaysia; these birds were said to have given the gift of fire to the Négritos Semang, and the woodpecker thereby became a sacred bird which the Semang people will not harm. This is probably linked to a superstition in Germany, where the burning in a fireplace of wood chips from a Black Woodpecker nest is believed to bring happiness.

Superstition and witchcraft often go hand in hand. The wrynecks' peculiar movements of the head and neck when cornered (see Breeding) have, not surprisingly, earned these picids the name of "snake-bird". This behaviour has also resulted in the Eurasian Wryneck being used in witchcraft in Britain, and probably elsewhere in Europe. In order to effect the return of a faithless lover, a wryneck was captured and tied to a wheel, which was then made to revolve. It is also of interest that, in the Middle Ages, the wryneck often went by the English name of "Inyx", a name which, by the transposition of letters, a common process in the evolution of language, became the scientific name for the genus, *Jynx*. Since the wryneck could also be used in witchcraft to cast a spell on an enemy, this gave rise to the modern word "jinx", meaning a bringer of bad luck. The innocent wryneck came to the fore again in the 1990's, following the reunification of Germany, when a politically opportunistic person was referred to as a *Wendehals*; only few people, however, realized that this name, "neck-turner", was also that of a cryptically coloured woodpecker that performs strange snaking movements with its head and neck.

Supernatural powers have been attributed to woodpeckers in many ways. Since these birds seem to know their way around in forests, which are often thought of as mysterious places, where a man could easily get lost, it is not difficult to understand how they came to be regarded as guides. When the Sabines, or Picentes, of ancient Italy migrated to Picenum, or "Woodpecker Town", their chiefs were led by a woodpecker; the name Picenum was retained as a reminder of the supernatural woodpecker's good deeds. Throughout the Americas, the woodpeckers' behaviour in spending most of their time on the trunks of trees, between the earth and the sky, led to their being regarded as spatial guides. The Klikitat natives, for instance, entrusted the sapsuckers alone to create two parallel upright links to the heavens with arrows. In tropical South America, the Tacana mythology includes the story that, if a woman's husband has become lost, the tapping or drumming by a woodpecker on a clay pot belonging to the woman will help to guide him on his way.

The use of augury was formerly widespread throughout the world, and involved many diverse creatures, including the Picidae. Many different interpretations were put on the augural animal's actions. In Guadeloupe, for example, the drum of a woodpecker could not only signify rain, but also foretell that somebody would die, or that a day's hunting would not be successful. According to the Waiwai Indians of Guyana, the nature of the sound made by a woodpecker foretold the sex of an unborn child, and was linked with the sound of their own drums, which they classified in two groups: the big ones produced low notes and were female, while the small ones with higher notes were male. So, if the bird gave a whistled "swiss-sis" the child would be a boy, but if it rapped out "tororororo" then a girl could be expected.

It is in Borneo, however, that the most renowned examples of augury are to be found. Here, the Iban, or Sea Dayaks, a polytheistic people, practised augury as what was to them a perfectly logical way of life. In Iban belief, the most important god is Singalang Burong, but he seldom reveals himself. Instead, he makes his will known through his sons-in-law, who appear in

Begging for food becomes more intense as the chicks grow. Furthermore, the parents become wary of approaching the youngster, with its increasingly large bill.

This male Black Woodpecker, however, has little choice, since this is one of the species which provides food, almost always insects, by regurgitation. In the final days before fledging, the adults enter the hole far less frequently, preferring instead to drop the food from the rim of the entrance, and they no longer remove excrement and other debris from the interior of the hole.

The well-developed plumage of this juvenile male suggests that fledging will occur soon. Even once the juveniles are on the wing, however, the parental duties are not over, as feeding by the male continues for up to a month. The sexual differences in this widely distributed Palearctic woodpecker appear on the plumage of the young at about ten days of age, although a small number of individuals, probably females, do not show any red on the head in the juvenile stage.

The insatiable demands for food by young woodpeckers can lead to conflict and aggression at the nest. What appear to be attacks on the parent, as shown by this young male Pileated Woodpecker, are common. Such behaviour, despite its apparent aggressive nature, is, however, simply an extension of begging behaviour, when the parent has not been so quick to supply food as the nestling had expected. Aggression does occur among siblings as they become older and more cramped in the nest, especially if food deliveries are not quite adequate. Moreover, various studies have found that in the case of the Pileated Woodpecker's Old World relative, the Black Woodpecker (*Dryocopus martius*), the nestlings not uncommonly die of starvation even when there appears to be plenty of food available. It is unclear whether sibling competition is responsible for this nestling mortality or whether another factor, such as disease or parasites, may be implicated.

Campo Flickers are one of a number of picid species which present food to nestlings by regurgitation. The adults forage for ants and termites during brood-rearing, breaking into terrestrial nests to obtain large quantities of food quickly. They carry the food in the oesophagus and proventriculus, and regurgitate it directly into the chick's mouth, even when the youngster is close to, or past, the fledging stage. Species which feed their young by this method tend to deliver food to the nest at longer intervals compared with other picid species. As well as the flickers, other woodpeckers which feed their chicks by regurgitation include the Dryocopus logcocks and the Picus species.

seven different bird forms. These comprise a kingfisher, two trogons, the Crested Jay (*Platylophus galericulatus*), the White-rumped Shama (*Copsychus malabaricus*) and, importantly, two woodpeckers: the Rufous Piculet, or *ketupong*, and the Maroon Woodpecker, *pangkas*. Significantly, the tiny piculet is the most senior of all seven augural birds, and is regarded as the guardian of man's welfare. This is perhaps less surprising when one considers that it is a common, restless and rather noisy bird around Bornean habitations, where its constant presence is taken as signifying that the piculet takes a keen interest in man's affairs. So important is the Rufous Piculet that its behaviour can determine the actions of an entire longhouse. The Maroon Woodpecker, although not so powerful an omen as the piculet, is still an augur that can have a great influence on the Iban.

Even in the middle part of the twentieth century, these beliefs were so strong that people almost feared that the birds themselves, as opposed to the god which they represented, were capable of causing harm. Whenever a Rufous Piculet or a Maroon Woodpecker was either seen or heard, great significance was attached to the event. If any of the augural birds flies from right to left across a person's path, or is heard on the right, this is a positive and powerful omen of good fortune; the reverse direction or side implies the opposite. Similarly, the bird flying in the same direction as the observer is a sign of good fortune, whereas one flying in the opposite direction is an inauspicious omen. In addition, the alarm calls of the two picids are associated with danger or are a sign of bad fortune. For example, when men are about to fell a forest to make a swidden, the alarm call of the Rufous Piculet indicates that they must abandon all work for the day and return to the longhouse; the highly inauspicious alarm call of the piculet, the senior of all augural birds, is a sure warning that, if felling continues, one of them will suffer serious injury from an axe. Nevertheless, a certain amount of freedom attaches to these omens, and the symbolism depends to a large extent on the interpretation placed on it.

A war party, on hearing the call of the Maroon Woodpecker, will welcome this as it foretells the triumphant shouts associated with the taking of an enemy head.

Although modern life, with its global methods of communication and the changing attitudes of humans, has to a great extent modified and altered the beliefs of many native peoples, there are still numerous surviving examples of how these seven birds ruled the life of the Iban people. With regard to the two picids, the following sample accounts should help to illustrate the importance that was attached to them. One afternoon in April 1950, a western anthropologist, J. D. Freeman, was conversing with a local Iban chief when a Rufous Piculet began to call close to the farmhouse in which they were sitting. The chief, named Kubu, said that he was not sure what the augury, which was heard by everybody in the house, meant, but that something was being told to the people. Later, after the evening meal, a woman of the house and her young son suddenly developed a gastric sickness; Kubu immediately announced that the *ketupong's* augury had been a warning not to eat the food, which must have been responsible for the illness. Four months after that event, in another instance, a woman who had arrived in a village after a boat journey along the river very soon died. Not long thereafter, it became known that, a short way down the river, a Maroon Woodpecker had uttered an alarm call and flown back and forth across the party's path; rather than stopping to observe the prescribed rituals, however, the party had ignored the augury and continued to paddle on to the village. The local augur, on hearing this, castigated the party's leader for having failed to take heed of the warning.

Another intriguing example, this time from the western side of the world, illustrates again how woodpeckers were thought to have special powers. In the latter part of the Middle Ages and later, it was believed that these birds knew about the magical properties of plants and their roots. Although it is not possible, from the tales told, to determine exactly which plants were involved,

the term "springwort" and similar ones are frequently used in this context. One could imagine that this may have referred to maiden-hair fern (*Adiantum*) or possibly to mandrake (*Mandragora*); in southern Germany, Solomon's-seal (*Polygonatum multiflorum*) seems a probability, and elsewhere it could have been caper spurge (*Euphorbia lathyris*). In any case, the plant was supposedly endowed with magical properties, and the Black Woodpecker knew where it grew. If a man wanted to acquire this plant, he had to find a Black Woodpecker's nest with nestlings and, when the parents were away, close off the hole entrance. The bird, on returning to feed the brood, would find the entrance barred and would leave. The man should then conceal himself beneath a red coat and wait for a day or two until the woodpecker returns with the root in his bill; the material blocking the nest entrance will fall out as soon as the bird touches it with the root. When the man then spreads the red coat at the base of the tree, the frightened woodpecker will release the precious root from its bill.

This legend is a very old one. In the first century AD, Pliny wrote that a woodpecker, by applying a certain herb, could cause a spike inserted in its nest entrance to drop out. The "woodpeck-

er's herb" was also a means by which a lover could secure a lady's affection: he would aim to obtain the herb in order to "open his desired lover's flank", enabling him to conquer her heart. The legend exists also in the West Indies, where the Guadeloupe Woodpecker performs the very same tricks with a magical herb; in this case, people who collect the dropped plant from the base of the tree acquire supernatural strength.

Another mysterious relationship between woodpeckers and plants, for which no obvious explanation suggests itself, involved peonies (*Paeonia*). It was said that the plant must be gathered at night, because if a man picked it during the daytime, and was seen by the woodpecker, he was in danger of losing his eyes; not only that, for, if he cut the root, it was very likely that his buttocks would fall off.

In somewhat similar vein, native Indian peoples in western North America considered woodpeckers to be the controller of sap, reflecting the role that they had in South American myths concerning honey. The mythology of the Chaco Indians of Paraguay and Argentina includes the story of the young girl Toba, who had an overwhelming desire for honey. As the youth Wood-

Immediately prior to fledging, the young woodpeckers almost fall out of the nest-hole in their eagerness for food. Indeed, some do topple out, the consequences almost always being fatal. This Pygmy Woodpecker chick is stretching so far outside the nest-hole that it is difficult for the female to get the food down its gullet while still maintaining a grip on the rough bark. In this photograph, the extensive fungal growth on the tree is a very obvious sign that the wood inside is decayed and soft, enabling this very small woodpecker to excavate a cavity with comparative ease. Pygmy Woodpeckers are the commonest picid in eastern Siberia, Korea and Japan, where they are found even in parks and gardens in major cities. The male has a small red spot at the side of the nape, but this is often concealed by overlying feathers.

Two features of the nest of the Black-backed Woodpecker, the second most northerly breeding picid in the New World, are particularly unusual.

As yet, however, there remains no convincing explanation for the characteristic "doorstep", the bevelled edge of the lower rim of the entrance hole, nor for the removal of the bark from the area around the nest-hole. Both may be defences against predators, although how they might act as such is not known.

The exposed wood certainly serves to draw attention to the presence of a nest, among human observers at least, since the hole is made rather conspicuous. This is a species that is associated with forest fires, its clutches often being initiated within a few days of the passage of a fire in late June.

[*Picoides arcticus*, near Machias, Maine, USA. Photo: John E. Swedberg/Ardea]

pecker was a well-known hunter of honey, Toba decided to marry him. As the story tells, however, honey was in the past the only food, but this ceased when Woodpecker, master of honey, changed himself into a bird and escaped human society forever. The White Woodpecker would seem to be the inspiration for this story.

The role of woodpeckers in providing holes is of vital importance to many other cavity-using animals (see Breeding). In

general, woodpeckers are very beneficial to humans, too, as they destroy large quantities of insects and larvae that are harmful to timber. The larvae of long-horned beetles, for example, are consumed by many members of this family, as also are injurious foliage-eating caterpillars. In South America, the White Woodpecker is a valuable ally of farmers who grow citrus fruits; in Brazil, for instance, it opens the nests of the indigenous bee *Melipona ruficrus* to get at the hymenopteran's larvae and pupae, which could otherwise wreak havoc on the farmers' crops. In this connection, it is worth noting that the type specimen of the stingless bee *Trigona ceophloe*, an insect capable of inflicting a strong bite, was discovered inside the stomach of a Lineated Woodpecker.

Although the role of woodpeckers as dispersers of seeds has not been fully evaluated, it is possible that a number of them, particularly *Melanerpes* and *Celeus* species, are of some importance in this respect. Furthermore, the part played by some of the forest picids, such as the *Dryocopus* logcocks, in breaking up large old logs and assisting in the recycling of nutrients should not be underestimated. On a broader level, the many and varied specializations found among the Picidae (see Habitat, Food and Feeding) make these birds excellent indicators of the general biodiversity and quality of habitats, especially in wooded environments. As a consequence, they have a great influence in determining the best management techniques for forests (see Status and Conservation).

Notwithstanding the beneficial effects that these attractive birds have on the life of humans, and the pleasure that they bring to many people, there are several aspects of the lifestyle and behaviour of certain species that bring them into conflict with man. One of the more obvious examples is the predilection of some woodpeckers for fruits and nuts (see Food and Feeding), which results in their entering commercial orchards and, in some cases, causing real damage. Some of the melanerpinés can at times invade fruit-growing areas in rather large numbers, and may then be responsible for fairly serious depredation of such crops as oranges, apples, bananas and papayas. In the past, Red-headed Woodpeckers in eastern North America were considered significant agricultural pests, and considerable numbers were shot; such persecution of this and other frugivorous woodpeckers still occurs today, although on a far smaller scale (see Status and Conservation).

Even before fledging, young woodpeckers sometimes scramble out of their hole, especially where the nest is in a cavity at the base of a branch. The parents of this young Eurasian Wryneck will continue to care for it for ten to 14 days after it has left the nest. Both nestling and adult wrynecks, if alarmed, slowly extend the head and neck and then quickly retract them, while emitting hissing sounds. This behaviour, unique to the wrynecks, has been interpreted as snake mimicry, and is the origin of the English name of the genus.

[*Jynx torquilla torquilla*, near Bavilliers, Vosges Mountains, France. Photo: J. P. Delobelle/Bios]

Nest sanitation is especially important for birds which rear their young inside holes. There is, however, considerable variation among, and even within, species as to which sex contributes the more to this task. This female Northern Flicker leaving the nest-hole is carrying a faecal sac mixed with other material from the cavity floor. Like the Golden-fronted (Melanerpes aurifrons) and Grey-faced Woodpeckers (Picus canus), among others, Northern Flickers, especially females, cease removing debris during the last few days before fledging. Other picids, such as the Great Spotted Woodpecker (Dendrocopos major), continue to clean out the cavity until the very end of the nestling period.

Vireo]

Crop damage by picids remains a problem of varying importance in several parts of the world. In the Neotropics, serious damage to sugar cane and cacao pods has been blamed on such species as the Cream-coloured, Blond-crested, Lineated and Robust Woodpeckers, which are said to perforate the pods and to return later to feed on the insects that have been attracted to them. It is far more likely, however, that the woodpeckers attack pods which are already infested with insects; observations revealed this to be the case when woodpeckers attacked *Cassia* pods in Asia, and the same probably applies in most other instances of such behaviour. In Europe, the Syrian Woodpecker not only attacks ripe apricots and prunes in order to reach the kernels, but also takes the flesh of certain citrus fruits, cherries (*Prunus*) and other fruit crops. This picid is also very fond of almonds and other nuts, and is capable of inflicting appreciable damage in commercial plantations of these. Moreover, in parts of the Middle East, it even sabotages the polyethylene pipes used for irrigation in orchards.

Another type of damage is sometimes caused by White-backed Woodpeckers in Japan, where individuals of the rare subspecies *owstoni*, in their search for wood-boring beetle larvae, not infrequently hammer into the bed logs used for mushroom-growing.

Much has been written over the years concerning the use by woodpeckers of artificial wooden substrates in which to excavate their holes. This behaviour seems to be most prevalent in the New World, particularly in North and Central America, where species as diverse as the Red-headed and Golden-fronted Woodpeckers, the Ladder-backed Woodpecker, the Northern Flicker and the Pileated Woodpecker are among the most frequent users of utility poles. The extent to which, through their actions, they do any real damage to these artificial structures is debatable. There are certainly some instances in which poles have been sufficiently weakened that they break off at the site where they have been hollowed out, this being caused mainly

by strong winds. In regions where poles are used more extensively by woodpeckers, as in parts of the Midwest, replacements made of cement and fibreglass have been erected, and attempts to protect wooden poles have included the use of wire or plastic mesh; in some cases, ropes have been hung from utility poles in an effort to simulate snakes. All of these measures, however, have met with limited success. Among other methods used to prevent woodpecker damage to utility poles in the USA, the most successful is probably the spraying of the wood with non-toxic repellent. Poles are frequently impregnated with creosote, but this generally results in reduced breeding success for any woodpeckers which use them, as the eggs and young die; if the creosote becomes "diluted" over the years, however, nesting success usually improves.

Similar utilization of poles, especially telephone poles, occurs also in the West Indies, where the Hispaniolan, Jamaican and Guadeloupe Woodpeckers excavate at least occasionally in such sites. Woodpeckers dig holes in wooden utility poles in Europe, too, although the habit is less common there. On the other hand, they can cause serious damage in parts of that continent by excavating into the styrofoam material used to insulate houses. The culprit in almost every case is the widespread and common Great Spotted Woodpecker, which hammers along the corners of houses and occasionally under the eaves, and easily drills through the thin outer insulating layer of resin and sand, enabling it to build its hole in the styrofoam itself in a very short time; such holes, incidentally, are apparently used only for roosting. It is probable that this behaviour is prompted by the hollow sound which the picid hears when "testing" the substrate.

An even more amazing event, and one which caught the headlines of the news media, occurred in June 1995, at the Kennedy Space Center in Florida, USA. Not long before the space shuttle *Discovery* was due to be launched, it was discovered that some 200 holes had been made in the rusty-brown foam insulation cov-

After about 25 days of life, the time has come when this young Eurasian Green Woodpecker must leave behind the relative security of the nest-cavity, and venture outside. Inevitably, this is often a clumsy process, the juvenile flapping to a nearby branch or to the ground in order to recover from its exertions.

The heavily streaked and spotted plumage that characterizes the juvenile of this species is clearly evident in these photographs. The adults of many members of the family provide much less food for their young during the day or two before the end of the nestling period, this presumably acting to encourage the chicks to leave the cavity. All nestmates leave within an hour or two of one another, and they remain in the vicinity of the nest for a while before moving a short distance to suitable feeding areas.

The Eurasian Green Woodpecker is one of several picids in which the fledged brood is often divided between the two adults, each one individually accompanying one or more of the offspring. It is worth noting that nest success is higher among the Picidae than among many comparable avian families, most woodpecker species typically fledging at least one young from 70-100% of nests. Total failure is, therefore, comparatively rare. The majority of losses occur at the egg stage or when the nestlings are small.

Bios]

Having left the nest-cavity, juvenile woodpeckers are dependent on their parents for up to a week or two, and in some cases even longer. They maintain their aggressive-sounding begging calls, constantly demanding food. This is the period when they are most vulnerable to predators. The Great Spotted Woodpecker is another species in which the parents often divide the brood between them, a phenomenon that seems to occur only in temperate zones. This male will continue to feed its offspring for about ten days, but several weeks will elapse before the juveniles leave the nest and explore more widely.

ering the shuttle's main fuel tank. The launch was postponed, and baffled scientists initiated an urgent investigation in order to identify the perpetrators of the damage, the reasons for it, and viable solutions to the problem. It was only later, after video cameras had been set up, that the culprit was caught. One or more Northern Flickers had acquired the habit of pecking holes into the insulation, tossing the foam aside as they worked, their actions thus being identical to those used when excavating into rotten wood. Various methods of dissuading the flickers were tried, some of them practical and direct, and others, such as the erection of signs reading "No Flickers Allowed", more a case of wishful thinking. A professional ornithologist was called in. The trouble was that the immediately surrounding habitat, with closely mown fields, was ideal for flickers, but just about all the suitable nest-sites had been taken over by the numerous introduced Common Starlings (see Status and Conservation). The insulating foam material, while very like rotten wood in colour and consistency, was only 10-15 cm thick and therefore not deep enough for a nest-cavity, so the flickers continued to peck in the vain hope of finding an area of adequate depth, thereby producing the many holes. After much thought and discussion, the most cost-effective solution seemed to be simply to increase NASA personnel's awareness of birds in the launch-pad area, and to implement various bird-deterrents. The total cost of the delay and for repairing of the damage ran to over one million US dollars. Earlier warnings of the potential of woodpeckers to interfere with operations at the Kennedy Space Center had not been heeded: there have been several incidents, from 1980 onwards, in which flickers and other picids have pecked holes in the insulation of pipes and model fuel tanks.

In essence, just about any suitable substrate, including log cabins, wooden houses, wooden shutters and similar structures, is likely to be subjected to woodpecker damage, at least locally. In Brazil and Argentina, for example, the Campo Flicker occasionally makes holes in rural adobe houses and in tile walls.

While the food-storing melanerpinies seem to prefer trees for use as granaries (see Food and Feeding), they will on occasion use other places. A group of Acorn Woodpeckers at the Santa Rita Lodge Nature Resort, in the Madera Canyon, Arizona, has chosen to drill its storage holes into the outer walls of wooden cabins, where overhanging eaves offer good protection. Fortunately, the occupants of the cabins are usually visiting

birdwatchers who, once they have become used to the sound of the woodpeckers hammering acorns into the holes, are happy to be able to watch the birds at close quarters.

In other situations, however, this may not always be the case. Woodpeckers hammering on buildings are sometimes deemed to be a nuisance by the human inhabitants of the area. As with picids which raid farmers' crops or damage agricultural installations or utility structures, they are persecuted locally (see Status and Conservation).

## Status and Conservation

Of the world's 216 woodpecker species, ten are officially classified as globally threatened, while the distinctive subspecies *ramsayi* of the Philippine Woodpecker, treated by some as a separate species, is also considered threatened. A further twelve species are listed by BirdLife International as near-threatened. Bearing in mind that many of the Picidae are forest-dwellers, these are not particularly large totals, although it is not unlikely that the lists will grow as the world's forests and other natural habitats come under increasing pressure from developers.

Of the threatened species, three are South American piculets, two are campetherine pied woodpeckers, as also is *ramsayi*, one is a colapine flicker, three are large campephilines, and the last is a Japanese island representative of the Picini. Seven of the threatened taxa live in Middle or South America.

Three woodpeckers are categorized as Critical, and two of these may already be extinct. These are the Imperial Woodpecker and the Ivory-billed Woodpecker, the two largest species of all the Picidae. The Imperial Woodpecker, a magnificent, huge woodpecker with black and white plumage, inhabited open pine forest on flattish plateaux throughout the Sierra Madre Occidental of Mexico. The male's striking red crest, replaced on the female by a black and extraordinarily recurved one, made this enormous picid quite unmistakable. It seems that the Imperial Woodpecker was never particularly common, having achieved an estimated maximum population of no more than some 8000 individuals, and indiscriminate shooting and habitat destruction over a lengthy period of time have led to its almost certain recent extermination. There are no confirmed reports of this picid since

1958, when it was seen in the state of Durango. A number of reported sightings have occurred since then, however, and several post-1965 reports were sufficiently convincing to provide a glimmer of hope that the woodpecker might not yet be totally extinct. In particular, a solitary female reported from north Sonora in 1993, a pair in central Durango in the same year, and a single male approximately 20 km from the latter site two years later, gave some ground for restrained optimism. On the other hand, the remaining habitat is so fragmented that any individuals which may still persist would have little chance of survival.

Although the Imperial Woodpecker has been recorded just below 1700 m, most sightings, both recent and historical, have been made at altitudes between approximately 1900 m and 3000 m. Within its original habitat, the woodpecker fed mainly on beetle larvae obtained from standing dead or partly dead pine trees, in which it also excavated its nest. Such foraging and nesting niches would always have been patchy and uneven in distribution, and it has been calculated that a single pair of these massive picids would therefore need an area of at least 25 km<sup>2</sup> in order to sustain itself and to breed successfully. In earlier times, when its habitat was relatively healthy and secure, the species was often seen in groups of four or more individuals. This has led ornithologists to deduce that, because adequate quantities of its larvae food probably became available at localized sites only for brief periods, which would occur at different times in different parts of the forest, the woodpecker may well have wandered widely in small groups in order to exploit these sites. If such a nomadic group contained, say, eight individuals, it would require at least 98 km<sup>2</sup> of continuous old-growth forest, something which nowadays simply does not exist.

In fact, a year-long survey of the pine forests of north-western Mexico in 1994 and 1995 proved unproductive. Not only were no Imperial Woodpeckers found, but the few remaining old trees that could have been useful to the species had been removed by loggers. There is now no continuous area of old-growth forest remaining anywhere in the Sierra Madre Occidental that is large enough to support a single breeding pair of this picid.

The tragedy of this species' almost certain extinction is that it could easily have been avoided. There can be little doubt that

shooting, carried out partly for "fun" but also because parts of the bird were thought to have useful medicinal properties, played no small part in the woodpecker's demise; this species had been hunted for a very long time, and this factor alone would have had a negative impact on a large bird, with a small population, living in a restricted range. The complete degradation and destruction of its habitat, however, ensured that the dwindling numbers continued to fall to unsustainable levels. Through lack of political will, and a refusal by the authorities to recognize the plight of the woodpecker and other indigenous species in the Mexican mountain forests, the wholesale removal of pine trees, both mature live ones for timber and, more importantly, dead ones for pulping, was allowed to continue unchecked. Not one suitable reserve was ever set up to protect the Imperial Woodpecker, a very sad reflection on the ability of man to look after the wildlife and biodiversity of the planet Earth.

Somewhat smaller than the last species, but still a huge woodpecker and equally striking in appearance, the congeneric Ivory-billed Woodpecker was thought already to be extinct in the 1990's. Indeed, there is a strong likelihood that that is now the case. This wonderful species, similar to its Mexican relative but with a white stripe on the neck, was once widely distributed in the south-eastern USA, ranging from Oklahoma and Missouri across to North Carolina and south to Texas and Florida. Its prime habitat in the USA was tall lowland swamp-forest. A separate subspecies is found only in Cuba, where it bred not only in lowland hardwood forest but also in pine forest in the mountains. Once again, this woodpecker's staple diet consists of wood-boring beetle larvae, for which it requires a good element of dead and dying trees. Not surprisingly, therefore, the population density was evidently always rather low, both on the mainland and in Cuba, as a breeding pair required at least 16 km<sup>2</sup>.

In the USA, the last confirmed records of the Ivory-billed Woodpecker were in the 1950's, although the species was possibly still alive there in the 1970's. Since then, intermittent reports of this woodpecker from the south-eastern parts of the country have always been found to refer to the superficially similar but much smaller Pileated Woodpecker, which is not uncommon in the region. A pair of Ivory-billed Woodpeckers said to have been

*The length of time during which the juveniles are fed by their parents, or accompanied by them, is unknown for most species, including the Hoffmann's Woodpecker. Here, a male is passing a fruit to a juvenile in the dry forest of Costa Rica. The young of several tropical members of this family, in both the Old World and the New World, are known to remain in the company of their parents for a protracted period, sometimes until the parents begin the next reproductive cycle. Furthermore, the immatures of social picids often remain with the family group for an extended period, in some cases for several years.*

[*Melanerpes hoffmannii*,  
Nosara Biological  
Reserve, Costa Rica.  
Photo: Rolf E. Kunz]

Many picids, apart from those tropical forest species that feed almost exclusively on ants and termites, take advantage of human-provisioned food. This behaviour is most frequent in Europe and North America, bringing a splash of colour and pleasure to garden birdwatchers. As these Black-cheeked Woodpeckers illustrate, however, picids across the world will accept the offerings. Sharing the fleshy fruit on a makeshift birdtable are a Clay-coloured Thrush (*Turdus grayi*) and a female Scarlet-rumped Tanager (*Ramphocelus passerinii*). Woodpeckers have learned to hang upside-down if necessary, and to sip sugar water from hummingbird (*Trochilidae*) feeders.

[*Melanerpes pucherani*, near Lake Arenal, Costa Rica.  
Photo: Rolf E. Kunz]

seen in 1999 in the Pearl River Wildlife Management Center, in Louisiana, could not be found in follow-up surveys. As is so often the case, the primary cause of this picid's extinction in the USA is destruction and fragmentation of its forest habitat. Even by the 1940's it had been reduced to a very small number of individuals, and forests have continued to be degraded and destroyed since then. In his superbly evocative writings, J. T. Tanner, who was, until his death in 1991, the leading authority on this species, described a forest wilderness that was "almost primeval", a virgin swamp-forest with many huge trees and an incredible diversity of wildlife. This was the Singer Tract in Louisiana, where Tanner and his guide, J. Kuhn, studied some of the last remaining pairs of Ivory-bills in a habitat which can only be imagined today. Even there, however, where eight species of picid lived, this beautiful woodpecker had disappeared by the mid 1940's.

The fate of the Ivory-billed Woodpecker's slightly smaller-billed Cuban subspecies, *bairdii*, is no better. By the early twentieth century, much of the island's forest cover had gone and the woodpecker was confined to the surviving tracts of forest of Cuban pine (*Pinus cubensis*) in the east. In 1948, a population was discovered in the Cuchillas de Moa Mountains, where six territories of this species were located in 1956; in that year, a total of eight pairs and one juvenile was present in the eastern mountains of Cuba. Unfortunately, political upheaval prevented further study there, and plans for the establishment of reserves were unfulfilled. When research resumed, in 1985, the only possible evidence of the species was the distinctive feeding marks left by the woodpecker, which uses a particular foraging technique in which it scales bark from dead trees. Much of the region's forest had been removed. Further expeditions in April 1986 located one bird at Ojito de Agua and a pair seen repeatedly at Cabezada del Yarey, but by 1991 only a single bird appeared to be left, and in 1992 and 1993, intensive fieldwork in east Cuba failed to locate any Ivory-billed Woodpeckers. It was also discovered that bark could be removed from the pine trees by heavy rain, so that bark-scaled trees could not be interpreted as a sign of the woodpecker's presence.

Yet again, habitat loss appears to be the reason for the disappearance of the Ivory-billed Woodpecker from its Cuban refuge. Almost no old-growth forest remains that is sufficiently extensive and intact to support the species. The single exception is an

area of apparently undisturbed pine forest high in the Sierra Maestra, south-west of the species' original range in eastern Cuba. It is, therefore, of great interest that this woodpecker's presence was reported there in 1998, although no confirmatory evidence has since come to light.

The third and last picid having a conservation status of Critical has a far less high profile than the previous two *Campephilus* ivory-bills. This is the Okinawa Woodpecker, which is found only on the island of that name in the Japanese island chain of Nansei-shoto. This picine woodpecker, although occasionally seen in coastal regions, is restricted as a breeding species to the subtropical evergreen forest lying along the mountain ridges in the central mountain chain of Yambaru, in the northern part of the island. Originally more widespread, it has lost much of its habitat and now breeds mainly in the area between the two mountain peaks of Nishime-take and Iyu-take. The breeding population here is extremely small, and in the early 1990's was estimated at a maximum of 70-80 individuals; the total population does not exceed 584 birds, and could even be below 150. As long ago as the 1930's the Okinawa Woodpecker was thought to be close to extinction.

This little-known woodpecker's decline can be attributed primarily to deforestation. It requires forest that is 30 years or more of age, and which contains tall trees with a diameter of at least 20 cm. Such habitat has long since been removed from the lower slopes, and logging has made inroads into the upper parts of the Yambaru. With the pressure on existing suitable habitat unceasing, principally as a result of dam-construction, agricultural development and the building of golf courses, along with the road-building associated with these, the rate of removal of old forest remains significant. Furthermore, the Okinawa Woodpecker's severely restricted range and extremely small population render it vulnerable to disease and to natural disasters such as typhoons.

This picid is present in small protected areas on each of the two mountains at the extremes of its breeding range, as well as in the protected area of Mount Yonaha. In north-eastern Okinawa, it has been found to occur at an estimated density of 12.1 birds per km<sup>2</sup> in the US Forces Northern Training Area, which offers some hope for its future survival. One is compelled, however, to conclude that, despite the fact that the

Okinawa Woodpecker enjoys legal protection in Japan, and notwithstanding the fact that Yambaru was designated as a national park in 1996, further action is needed if it is to be saved from extinction. Conservation organizations have already purchased some sites where the species is known to be present. In particular, there is an urgent need also for the establishment along the island's central ridge of special protected areas which include all mature forest with an age of 40 years or more, and for the prohibiting of logging in forest that is more than 25 years old. Further conservation measures proposed include the planting of forest "corridors" to connect forest fragments, and the provision of nestboxes in young secondary forest. The institution of a conservation programme, using the Okinawa Woodpecker and the Endangered Okinawa Rail (*Gallirallus okinawae*) as examples by which to inform the public, is a further suggestion deserving of serious consideration.

While thought not to be at quite such high risk as the preceding three species, Fernandina's Flicker is, nevertheless, considered to be seriously threatened and is listed as Endangered. It is found only in Cuba, where its population is extremely small and fragmented. Although the woodpecker seems never to have been very common there, it was formerly widespread on the island. During the course of the twentieth century, however, habitat loss has reduced it to a few localized and small populations in the three provinces of Pinar del Río, in the west, and Matanzas and Camagüey in the central portion of the island. The species may also still survive in several other provinces, and a recent record from a new locality, La Platica in Sierra Maestra, in south-east Cuba, suggests that there could be small, as yet undiscovered populations elsewhere. By far the largest population is at Zapata Swamp, in Matanzas, where there may be 120 pairs, and where, uniquely, loose colonies are occasionally encountered. Over the island as a whole, however, the flicker's numbers have declined, and the maximum total population in the year 2000 has been estimated at no more than 400 pairs, probably only 300 and quite possibly even fewer than that.

Rather open woodland and pasture with palms appears to be this flicker's preferred habitat, but it can also be found in denser woodland. It is closely associated with palm trees, especially the palm *Saval parviflora*, which it utilizes for nesting. Both dead and live palms are accepted, and it has been suggested that these

trees are chosen because they are often invaded by fungus, making the wood softer and more suitable for excavation. These trees are used also by the Cuban Amazon (*Amazona leucocephala*), a near-threatened parrot, and the two species often nest in the same individual palm.

Clearance of forest for agricultural purposes, as well as logging, have been at least partly responsible for this woodpecker's decline, and continue to be so, but there are other factors which may be just as important. In the Caribbean, hurricanes can have a major and devastating effect on dead palms, which are quite incapable of withstanding the blast of such mighty winds. In addition, bird-trappers seeking young parrots frequently push over down dead palms in order to collect the nestlings, irrespective of whether or not there is a flicker's nest in the same tree. The result is that the flicker loses not only its brood of young, but also a good nest-site. Competition with other hole-nesting birds, including, especially, the Northern Flicker and two other woodpeckers, adds to the pressure. A further potential problem is nest predation by the West Indian Woodpecker, but the significance of this has not really been assessed.

Although the whole of the Zapata Swamp is a reserve, the available resources for ensuring its effective protection are totally inadequate. In spite of the Cuban government's sterling efforts to secure the country's wildlife, including the creation of many reserves, funding this work has proved to be very difficult. Among the conservation measures proposed with the aim of safeguarding the future for Fernandina's Flicker, that of producing posters and displaying them in villages in areas where the species still exists seems to be the most promising. It should certainly raise awareness of the plight of this rare woodpecker. Additional measures that have been suggested are the implementation of a nestbox scheme in the vicinity of known nesting areas, and a census of all current and former sites where the flicker is known to have bred in order to determine its exact range and status. Detailed study of its feeding and nesting requirements may also help to explain just why the species has declined as it has.

Five of the remaining seven globally threatened picid taxa, all of which are classified as Vulnerable, are found in the New World. In North America, the Red-cockaded Woodpecker is particularly well known as it has been intensively studied in the last

Woodpeckers have a strong relationship with people, adapting to take advantage of gardens, houses and farming. If humans have assisted populations of some species, they are also largely responsible, through forest destruction, for the fact that eleven picid species are globally threatened, and a further dozen listed as Near-threatened. Two are almost certainly extinct, and there is a high risk of several others going the same way in the next hundred years. The Red-necked Woodpecker, shown here, is not yet at risk but, since thousands of hectares of its Amazon rainforest home are cleared every year, it could well become so.

two decades. Its status as threatened is due to the fact that the remaining populations are small and appear to be decreasing at a rapid rate. Once distributed over all of the south-eastern USA, this woodpecker is now found in only about 30 isolated populations, with its main strongholds in South Carolina and Florida. Some 4700 groups are known, six of the populations accounting for half of these, and the combined total of individuals is approximately 11,000. Much of its ecology and biology, such as its reliance on fire-sustained forest, its requirement for old trees, and its co-operative group-living behaviour, has been discussed in detail earlier (see especially Habitat, General Habits, Breeding). The clearance of these forests, and forest management based on economics, have over many years had a hugely detrimental effect on this species, leading in particular to increased fragmentation of its habitat. A population decline of over 20% was recorded in the 1980's alone.

The Red-cockaded Woodpecker lives in a rather special type of forest. Its typical habitat is mature open pine forest that maintains its specific tree composition and structure through the action of frequent lightning-induced fires. These fires occur naturally at intervals of one to five years, and they destroy hardwood species which would otherwise encroach on these pine stands. The seven pine species involved, chiefly longleaf (*Pinus palustris*) and loblolly pines (*P. taeda*), are able to persist in these fires. The woodpeckers require old trees at least 70 years of age for nesting. They have to expend much effort to construct the nests, and this seems also to be one reason why Red-cockaded Woodpeckers remain at a particular location even when hardwood has encroached, or after the surrounding forest has been cleared. The consequence of this site-tenacity is that the impact of severe changes in the habitat may take effect on the woodpecker population only some years later. The main problem for the species, and the reason for its Vulnerable status, lies in the fact that the pines are a much sought-after timber for industry. Modern forestry leaves little room for the woodpeckers, and efficient harvesting schemes do not allow for the old and tall trees which the woodpeckers need. The plans that were prepared to aid the recovery of the woodpecker were only partly implemented

and, although heavily criticized by experts, they were not revised to rectify the flaws contained within them.

Besides habitat degradation, another concern for the survival of this species stems from the fragmentation of its population. The creation of corridors between isolated populations has been suggested, but these proposals were never taken up. The genetic and, ultimately, the conservation consequences of such fragmentation have been hotly debated, but no conclusive result has emerged. As a singular event, hurricane "Hugo" in 1989 created havoc in the Francis Marion National Forest, South Carolina, which harboured the largest and healthiest population of Red-cockaded Woodpeckers. It took much effort by conservationists and several legal cases before more effective measures could be initiated, at least on federal lands, and even then management has not always been appropriate for this picid.

J. Jackson, one of the leading authorities on the species, lists three measures that he believes to be major breakthroughs for the management of the Red-cockaded Woodpecker. They are, respectively, the use of metal plates that restrict the size of the nest-cavity opening, the catching of young females at their natal site and transplanting them to groups without a female, and the provision of artificial cavities. The cavity-restrictors were suggested and first applied by the group led by J. H. Carter, III, in North Carolina. These metal plates protect the cavity entrance and leave open only the lower rim, where the woodpeckers cling and contact the entrance when entering the hole. The restrictors help to fend off cavity-using species that usurp Red-cockaded Woodpecker nests and roosts, which include flying squirrels, Red-bellied and Red-headed Woodpeckers, Northern Flickers and Common Starlings. The restrictors are an effective means of preventing hole take-overs by other species, and they also prevent Pileated Woodpeckers from enlarging existing cavities. Other measures involve the removal and selective cutting of hardwood. Nevertheless, many problems still remain. Most efforts are concentrated on public land, and they are often only poor substitutes for "the real thing"; for instance, forests are burned in winter rather than, as they should be, in summer. Moreover, the official exemption of private landowners from compliance with the US Endangered Species Act led to this woodpecker's numbers declining rapidly in some places, although this problem has been addressed to some extent with the introduction of various management incentives. A further problem is the infestation of cav-

Several woodpecker species, even though not identified as being of high conservation concern, have a limited distribution. Knowledge of the status or ecology of many others is very scant, and for many tropical species, especially those in South America, few studies have been undertaken. One such example is the Rufous-headed Woodpecker, which has a small range, straddling the boundaries of Ecuador, Peru, Brazil and Bolivia; over 3000 km away, in east Brazil, the race *obrieni* has not been seen since 1926. The humid forest in which this woodpecker lives is difficult to penetrate, making surveys and biological studies difficult. It would be tragic to lose any species simply because we barely know of their existence.

[*Celeus spectabilis spectabilis*, Intuto, Rio Tigre, north Peru. Photo: J. Alvarez/VIREO]

The Caribbean islands host eight species of Picidae that are found on only a single island or archipelago. One of these is the Antillean Piculet, a restricted-range species which occurs only in the Hispaniola Endemic Bird Area. Fortunately, it is a common bird in most of its range and is not, therefore, considered to be at any immediate risk. This contrasts with the situation of two other Caribbean picids: the Guadeloupe Woodpecker (*Melanerpes herminieri*) is considered Near-threatened, while the Fernandina's Flicker (*Colaptes fernandinae*) of western Cuba is Endangered.

[*Nesocites micromegas micromegas*, Lago Enriquillo, near Duvergé, Dominican Republic. Photo: Barry Wright]

Although not really rare, the Buff-necked Woodpecker is now very patchily distributed across South-east Asia, where huge areas of its dense forest habitat have already been destroyed. This small, chocolate-coloured woodpecker, here seen clinging to a fungus-covered tree in the evergreen forest of north Borneo, is probably not uncommon in the more upland parts of its range, but further deforestation in these higher regions could quickly place it at considerable risk. In order to draw attention to this very real possibility, the species is listed as Near-threatened.

VIREO]

ity trees by southern pine beetles (*Dendroctonus frontalis*), leading to the death of the tree, which, as it no longer produces resin, becomes of no use to Red-cockaded Woodpeckers.

Several resolutions are needed if this species is to survive in the twenty-first century. Monitoring of all existing populations, especially where these are already managed, is clearly necessary. Otherwise, it would seem highly desirable also that habitat management be at the ecosystem level, rather than, as it has been, site-specific. In addition, ongoing study of the factors that influence the success of translocation experiments could reveal important data on this species. Equally importantly, however, there appears to be a real need for conservation bodies to come up with plans that are both acceptable for private landowners and beneficial to the Red-cockaded Woodpeckers themselves.

Considerably less attention has been paid to the Neotropical Helmeted Woodpecker, which is restricted to east Paraguay, north-east Argentina and south-east Brazil. This species lives in primary forest and lowland Atlantic forest, habitats which have suffered extensive and long-term clearance, fragmentation and degradation. It is probably reasonable to assume, therefore, that it has undergone a significant and rapid decline in the last 50 years, hence its classification as Vulnerable. A difficulty with this species, however, is that it is by no means easy to locate, except during the brief period of the year when it is heard calling, and it is very likely that it has been under-recorded in recent years. A number of intensive searches have revealed, for example, that this handsome woodpecker occurs in both lowland and montane forest, and also in selectively logged areas. It has also been recorded in gallery forest, and even in small patches of degraded forest. Numerous reports since the early 1990's include that of a pair observed in 1998 in the Brazilian state of Santa Catarina, where no Helmeted Woodpeckers had been seen since 1946. All of these encouraging reports suggest that this species, although nowhere common, is not so scarce as was previously believed. It is present in at least 15 protected areas throughout its range, and is a legally protected species in Brazil. Further studies aimed at clarifying its distribution and status may possibly uncover a larger world population than is indicated by the present conservative estimate of 10,000 individuals.

It cannot be an exaggeration to say that the three Vulnerable piculets, all of them in South America, have received even less

publicity than the last species. The Speckle-chested Piculet (*Picumnus steindachneri*) is known only from a small area of the Andes in northern Peru. Within its tiny range, covering some 7000 km<sup>2</sup>, it has been recorded at no more than five sites, and it seems to have disappeared from at least one of those. This piculet lives at altitudes between 1000 m and 2300 m, where it inhabits epiphyte-laden, humid tropical and subtropical montane forest and tall second growth. Logging has been carried out in this region since the 1930's or earlier, although extensive deforestation for the commercial production of coca in the early 1980's, which threatened to destroy most of the natural habitat, appears to have ceased. Nevertheless, expansion of the human population has continued, accompanied by extensive clear-cutting and selective logging of the forests inhabited by this Vulnerable piculet. The south-east of its tiny range is now dominated by agricultural land and pasture, with forest remaining only on the highest slopes. Although the Speckle-chested Piculet occurs in the Alto Mayo Protected Forest, where it appears to be fairly common at one locality, Abra Patricia, it is not safe there, for there has been no cessation of forest clearance in this reserve. Conservationists have already discussed the situation with local leaders, and used media interviews and other methods to inform the local people of the urgent need for protection of the region's forests. This could be further promoted through co-operation with agricultural bodies, for whom the protection of the Alto Mayo watershed is of importance for the sustainability of farming. At the same time, this species' population status and ecological requirements need to be assessed, which would be greatly helped by additional surveys of the isolated east Andes ridges in this part of Peru.

The two other threatened picumnines, the Tawny Piculet and the Ochraceous Piculet, have very small ranges in north-east Brazil, where both have suffered from massive and unrelenting destruction of their forest and *caatinga* habitats. The Tawny Piculet's range is restricted to an area of no more than 470 km<sup>2</sup> in five states, where this scarce species is known from no more than ten localities, and has probably already disappeared from some of those. What little remains of the deciduous, semi-deciduous and secondary stands which it inhabits in the Atlantic forest is fragmented and subject to continuing exploitation, while grazing and burning has destroyed much suitable habitat in the *caatinga*. The Ochraceous Piculet is confined to north-central Ceará, where the

very few records are from just three sites, but it appears to be not uncommon locally. It lives in semi-deciduous forest and adjacent tall *caatinga* on hillsides, at up to 1000 m, and potentially suitable habitat has been greatly reduced through agricultural expansion, grazing and burning. In some areas, removal of forest has been virtually complete, while the remaining habitat is under threat from the construction of holiday homes. Both piculets occur also in degraded scrub or edge, the Tawny Piculet regularly so. The latter is present in five protected areas, at one of which, the Pedra Talhada Biological Reserve in Alagoas, reforestation with indigenous trees is an encouraging step that has been supported by local people, and guard patrols ensure that illegal actions do not occur. The Chapada do Araripe in south Ceará is apparently another important site for this species. Although the Ochraceous Piculet occasionally forages in degraded edge habitat with exotic bamboo and abandoned orchards, this is probably unusual. One of this piculet's known localities, in the Serra do Baturité, was granted protection in 1991, but with possibly limited success in safeguarding the species' remaining habitat there, although some local hotels in the region have had more success in this respect. For the effective conservation of both piculets, further survey work aimed at assessing their distribution, status and ecology is required, along with the proper protection of all appropriate sites.

Only two globally threatened picids are found in the Old World. The Arabian Woodpecker, with a small and probably declining population of fewer than 10,000 individuals, is at best rather uncommon and in some parts of its range is decidedly rare, with densities varying from 0.1 to 1.0 adults per square kilometre. Its woodland habitat on the western edge of the Arabian Peninsula has become highly fragmented following centuries of human colonization and its associated activities. Clearance for agriculture and building, as well as cutting for firewood, is a continuing process, and the result is often the removal of the large trees which this woodpecker prefers for its nest-sites. This is sometimes compounded by the effects of heavy grazing, which can prevent the regeneration of trees. Although many wooded areas in this part of the world have long been protected from over-exploitation, primarily as a source of fodder in times of

drought, the traditional management of them has been largely abandoned in more recent decades as it has become easier to obtain supplies of animal feed. The Arabian Woodpecker occurs in at least two officially protected areas. The designation of additional such sites, the encouragement of non-intensive, traditional methods of woodland management, and the raising of the profile of this Vulnerable species in its Arabian homelands would all help to secure its future survival.

The final one of the eleven globally threatened woodpecker taxa is the distinctive Sulu Islands subspecies *ramsayi* of the Philippine Woodpecker. With a very small range, currently estimated at only 1760 km<sup>2</sup> and decreasing, this picid gives genuine cause for concern; it is currently listed as Vulnerable. Its range originally covered eight islands in the Sulu Archipelago, between the Philippine island of Mindanao and north-east Borneo, but it appears now to be confined to perhaps just one, Tawitawi, and even there its continued presence has been confirmed at only three localities. From having been widespread and abundant in the first half of the twentieth century, this small woodpecker has become scarce, with a severely restricted range. It inhabits forest edge and clearings, mangroves and cultivations, but is sometimes found also in primary forest; its true habitat preferences are, however, unclear. The cause of this woodpecker's rapid decline is the familiar one of habitat destruction, which in this case has been extremely extensive and, on some islands, more or less complete. Even in its remaining stronghold of Tawitawi, the forest that is left is highly degraded and fragmented, and there are plans to replace the final surviving patches with commercial plantations of oil palms (*Elaeis guineensis*). With uncontrolled logging of the little remaining forest in the mountains almost certain to lead to expanding human settlement, and the attendant conversion to agriculture of any forest still left, the prospects for *ramsayi* do not appear at all good. Despite initiatives to raise awareness of the importance of conserving wildlife and biodiversity on Tawitawi, no formally protected areas exist anywhere in the Sulu chain. Moreover, military activity and other human problems in the region conspire to make conservation efforts a very difficult and dangerous operation. Organized campaigns and surveys are urgently needed if this picid, which would perhaps be better classified as Endangered, is to survive the constant and increasing pressure placed upon it. Even though it appears to tolerate degraded habitats, there is no doubt that its total numbers have continued to fall at a rapid rate. The fact that some recent authors have regarded *ramsayi* as a distinct species, under the name of "Sulu Woodpecker", could aid conservationists in their attempts to gain protected status for any sites that support populations of this distinctive brown-backed picid.

In addition to the eleven globally threatened taxa discussed above, there are twelve near-threatened species which should not be ignored. Seven of these are found in the Neotropics, including the Caribbean. The Rusty-necked Piculet (*Picumnus fuscus*) is confined to *várzea* forest straddling the border between north-east Bolivia and Brazil, while the Mottled Piculet is found mostly in lowland evergreen and mixed forest in south-east Brazil and adjacent parts of Uruguay and Argentina. The former may be not uncommon, but increasing human settlement along the largely uninhabited banks of the Guaporé river could become a threat. The Mottled Piculet's habitat has for years been subject to clearance for agricultural and other purposes, and is currently suffering even more from the effects of urbanization; in Argentina, the few areas of forest known to harbour this species would be flooded if permission is granted to build a proposed dam on the Río Uruguay.

Among the Picinae, the poorly known Choco Woodpecker (*Veniliornis chocoensis*) of west Colombia and north-west Ecuador has already lost more than a third of its habitat of lowland evergreen forest, and the rate of deforestation is increasing alarmingly; in the absence of controls on forest clearance and human activities, the conservation status of this picid could well become Vulnerable. Much the same applies to the Guayaquil Woodpecker (*Campephilus guayaquilensis*) living in the same general region, but extending southwards to north-west Peru, where it requires dry deciduous and humid forests in the lowlands and up

Only 22% or less of the earth's original forest remains intact. Of the 902 threatened bird species which depend on forest habitats, 93% occur entirely in the tropics, and 82% in moist forest. This is thus an important habitat for a range of species, including the little-known Yellow-browed Woodpecker, an apparently shy species of east-central South America. This attractive woodpecker inhabits humid forest, much of which has already been cleared by bulldozers or destroyed by uncontrolled fires, in both cases with the aim of agricultural expansion. This species is commoner in south-east Brazil, where montane forest has suffered less, but this situation could easily change. Hence, it is accorded Near-threatened status.

[*Piculus aurulentus*,

The Knysna Woodpecker is a restricted-range species, present in the South African Forests Endemic Bird Area.

It occurs only along a narrow zone of the south-facing coast and, although locally common, it is generally rather sparsely distributed. By the end of the nineteenth century, building development and sugar-cane farming had already reduced the total area of its bush habitat, and hence its range, and the losses have continued since then. The global population of this unobtrusive woodpecker is estimated at no more than 1500-5000 individuals, all of these now contained in an area of some 50,000 km<sup>2</sup>. It appears that perhaps more than half of these nest in nature reserves, ■ land-use proving to be increasingly important to the world's rarest birds. The Knysna Woodpecker is considered a Near-threatened species. So long as sufficient of its forest habitat can be preserved and effectively protected, it should be possible for this species to survive.

[*Campethera notata*,  
Eastern Cape,  
South Africa.]

Photo: Warwick Tarboton]

Of the 31 piculets of the subfamily Picumninae, three are classed as Vulnerable and a further two are considered Near-threatened. All five are Neotropical species having a very small range, the largest being that of the Near-threatened Mottled Piculet.

This sparsely distributed species of south-east Brazil, Uruguay and north-east Argentina prefers lowland evergreen and mixed forest, which has been subject to clearance for many years. More recently, increased pressure has resulted from South America's expanding human population, both directly, from urbanization, and indirectly, from proposals to dam the Río Uruguay to produce electricity.

[*Picumnus nebulosus*, Rio Grande do Sul, Brazil. Photo: J. Dunning/VIREO]

to 1800 m on the west Andean slopes; the extreme fragmentation of these habitats, leaving very few, very small forest patches, could easily push this woodpecker, which occurs naturally at low densities, into the threatened category. Farther south, in south-east Brazil and neighbouring parts of Paraguay and Argentina, the Yellow-browed Woodpecker (*Piculus aurulentus*) has already lost much of its forest habitat, and surviving patches are increasingly being destroyed by additional clearance and through such factors as uncontrolled fires; montane forest in south-east Brazil appears to have remained more intact, and for the time being serves as a relatively safe refuge for this species, but for how long will this be so? To the west, in the Chaco of south-east Bolivia and west Paraguay to north-central Argentina, the rare Black-bodied Woodpecker has declined in many areas and seems to have been reduced to two main populations, one in the Argentine provinces of Córdoba and San Luis and the other in the central Paraguayan Chaco; apparently few survive elsewhere, where clearance of woodland has been extensive, but further research may uncover useful details of this woodpecker's habitat preferences, which are not yet fully understood.

In the Caribbean, the Guadeloupe Woodpecker was rather poorly known until relatively recently. It is found in evergreen and semi-deciduous forest, swamp-forest and mangroves on both parts of the island, but much of its ecology and biology remained undescribed until the end of the 1990's. This situation has now been rectified by the magnificent work of P. Villard, whose in-depth and ongoing studies of every aspect of this species' life are a model for ornithological research and investigation. He has estimated this species' total population at about 10,330 pairs. The woodpecker has long been protected on the island, but, since it is considered a bad omen by hunting parties (see Relationship with Man), it is still sometimes shot. More importantly, the threats posed at present by continuing deforestation, especially on Grande-Terre, the eastern part of Guadeloupe, need to be addressed. Even in the island's national park, felling is permitted for tourism purposes. An essential priority is, therefore, that non-fragmented forest areas with suitable nesting sites in the form of dead trees and palms be preserved, a measure which is of particular importance in view of the damage that can be wreaked, both here and on other Caribbean islands, by hurricanes. The possible detrimental effects of pesticides and other biocides have not yet been fully elucidated, nor has the potentially serious problem of introduced rats (*Rattus*) been assessed. As is so often the

case in the modern world, however, probably the single most important issue is effective habitat protection, without which the excellent work of Villard and other dedicated scientists could prove to have been fruitless.

Africa has no globally threatened woodpeckers and only a single near-threatened one. This is the Knysna Woodpecker (*Campethera notata*), restricted to lowland coastal areas of southern and eastern South Africa. Here, the clearance of forest and bush for human settlements and agriculture had already reduced the species' range by the start of the twentieth century, since when much additional habitat has been lost. Although this woodpecker occurs in open country with large trees, and extends slightly inland, it is distributed mainly in coastal woodland, dense bush and *Euphorbia* scrub. It is thinly dispersed here, where suitable sites for hole-excavating may be rather sparsely scattered. Hence, within its total range of some 50,000 km<sup>2</sup>, this picid's global population is thought to lie between 1500 and 5000 individuals, of which about 30-60% probably live in nature reserves. Such a small population requires regular monitoring, the more so as the species' range becomes further reduced. Although not officially considered to be at any risk, the closely related Mombasa Woodpecker, with its restricted range on the East African coast from extreme south Somalia to north-east Tanzania, could be prone to population decline if its coastal woodland habitat suffers damage in any way. While it seems at present to be reasonably common, any further erosion and degradation of the habitat could change this.

Finally, four near-threatened woodpeckers occur in the Oriental Region. The Andaman Woodpecker (*Dryocopus hodgii*), found only on the Bay of Bengal island group of that name, is common enough in the evergreen forest where large trees remain. More recently, however, rapid human population growth on the larger islands, bringing with it logging and the conversion of forest to agricultural and grazing land, is becoming a serious threat. It would seem wise to monitor the woodpecker's numbers and, if necessary, to take action to prevent further loss of forest habitat. In South-east Asia, the evergreen and semi-evergreen forests of Laos are inhabited by the locally common Red-collared Woodpecker (*Picus rabieri*), which also occurs, uncommonly, in parts of adjacent Vietnam. This species, which generally lives below 700 m but ascends locally to about 1000 m, is in some places found in tall mixed deciduous forest, and is able to survive even in logged and disturbed forest, so

About 10,000 pairs of Guadeloupe Woodpeckers live on the 1700-km<sup>2</sup> archipelago.

The fragmentation of forests and mangroves, even within the country's national park, have given this Near-threatened picid an uncertain future, although it has adapted to all forest types. A more serious problem is that of hurricanes, which may become more severe and more regular as the climate becomes less stable; these cause major destruction of habitat and nesting sites. In addition, the potential problem of introduced rats (*Rattus*) needs to be investigated, and the birds are still sometimes shot illegally by superstitious hunters.

Bios]

long as the forest still contains some large trees; indeed, there is some evidence that, at least in some areas, it may prefer these latter habitats. However, the degradation and destruction of lowland forest that continue within this species' small range give sufficient cause for concern.

Habitat loss is a considerable problem facing many bird species in southern Asia, including two members of the Picidae. The Olive-backed and the Buff-necked Woodpeckers are distributed from southernmost Myanmar southwards through the Malay Peninsula to Sumatra and Borneo. The former inhabits mangroves, and lowland and hill forests, while the Buff-necked Woodpecker is a denizen of evergreen and semi-evergreen lowland forest and peatswamp-forest, both picids occurring up to about 1200 m. Attention has rightly been drawn to the massive destruction of lowland forest that has taken place, especially in the Sundas, and it is forecast that primary forest in those islands is likely to have disappeared altogether by the year 2010; significant habitat loss is also a major problem in Thailand and Peninsular Malaysia. Currently, both of these woodpeckers appear to maintain reasonable populations in the higher parts of their ranges, and the Buff-necked Woodpecker can be found also in secondary formations, but any extension of deforestation to the more elevated parts of the region would place these and many other wildlife species at considerable risk.

Several interesting facts emerge from what has been discussed in the preceding paragraphs. A number of woodpeckers are flagship species for conservation. The almost certain extinction of the North American Ivory-billed Woodpecker is a widely publicized event. The similar fate of its spectacular Mexican relative, however, has received much less publicity, and this is also true in Europe with regard to the local extinction, in Sweden, of the Middle Spotted Woodpecker. The Red-cockaded Woodpecker is undoubtedly the most renowned flagship species of forest preservation in the south-eastern USA. Many of the Picidae live in primary forest, a habitat which is globally threatened, especially in the tropics, and is vanishing at a frightening rate. A large number of this family's species and well-differentiated subspecies are potentially at risk because they are restricted to "islands", including isolated mountain ranges. Little is known about the ecology and population biology of rainforest species, and many of the island woodpeckers are poorly known.

The general trend for the survival of woodpeckers is, however, much better than it is for many other birds. A recent survey

by P. M. Bennett and I. P. F. Owens showed that extinction risk is not randomly distributed among bird families, and that the Picidae is the only avian family that contains significantly fewer threatened species than would be expected even if that risk were randomly distributed. This may, of course, be merely a result of lack of accurate and recent information. On the other hand, it may equally reflect the remarkable ecological and behavioural plasticity of most woodpeckers. Many picids fare well in landscapes modified by humans, and some can even profit from human activities. This is especially true for those which prefer more open habitats. In fact, those woodpecker taxa which are threatened, or near-threatened, share the common factors of a small

Arabia may seem an unlikely region to host a tree-dependent picid, but its forested south-western escarpment is the sole home of the Arabian Woodpecker. Human use of resources always avoided overexploitation, so that the woodland provided fodder at times of drought. With manufactured livestock feed now available, however, traditional management has been abandoned, resulting in a reduction in the amount of habitat suitable for the woodpecker. Maintaining traditional agro-forestry practices could be vital for the future of this Vulnerable species' small population.

NWRC Saudi Arabia]

range and the requirement for more or less closed forest with a very specific tree-species composition and general ecology. Yet even these species may be tolerant of human activities, so long as they do not change the quality of the habitat. Red-cockaded Woodpeckers, for instance, become tolerant of loud noise, and groups are known to survive on golf courses, on interstate rights-of-way, and in suburbs.

In Europe, woodpeckers are affected by human activities to varying degrees. None of the ten species is threatened, but some of them have suffered losses. The Eurasian Wryneck is a species which originally profited from human activities, as open woodland and orchards are very suitable habitats for it. Nowadays, however, these habitats are continually being destroyed, mainly because of the increasingly intensive and industrial methods of modern agriculture and forestry, which leave no room for old orchards and mixed hardwood forest. Lack of suitable nest-sites is another cause for concern, and the still heavy use of insecticides takes its toll, too. Other reasons for the severe decline of the species in central Europe may be climatic changes, or may lie in the African wintering grounds. Much less clear-cut is the status in Europe of the globally widespread Grey-faced Woodpecker; it has declined in many parts in its European range, while in others it has apparently increased. The precise habitat requirements of this species, which occupies deciduous forest, are still not fully understood, but natural, large and mature deciduous forest at middle elevations seems to hold the main source populations. As the two preceding species, the Eurasian Green Woodpecker requires meadows with plenty of ants, a habitat that is threatened by eutrophication, the use of pesticides, and a regime of either too much or too little cutting; the species has declined in many areas and is potentially at risk, despite its apparent abundance in some parts of the continent. The Black Woodpecker, despite its large size,

seems not to be under immediate threat. On the contrary, it has extended its range westwards since the 1980's and has colonized many parts of the continent; the fact that its expansion has not reached Britain may be due simply to the absence there of the woodpecker's staple food of *Camponotus* ants. This species is important for the wellbeing of many other forms of wildlife (see Breeding), as it provides nest-sites for, among others, Eurasian Jackdaws (*Corvus monedula*) and Stock Doves (*Columba oenas*), several bat species, and dormice. Its future in Europe can be regarded as secure, provided that mature forest with sufficient nest trees remains available.

Still in Europe, a species of great concern is the Middle Spotted Woodpecker, since it has suffered from forest-dieback insofar as this has also affected oaks. Old oak forests have become a rare natural habitat for several reasons, and preserving them is the main management measure that can be taken, while the protection of species-rich riverine forest is also important. Locally, this species is threatened because of the loss of old orchards. One of Europe's largest picids, the often overlooked White-backed Woodpecker, depends on large montane forests that are little influenced by forestry; in eastern Europe, however, this is a lowland species, and it is mainly these populations that are threatened by severe habitat loss. At the eastern extreme of this woodpecker's world range, the subspecies *owstoni*, confined to the island of Amami in south Japan, inhabits montane evergreen forest, where its small population is considered to be at risk. Another pied species, the Lesser Spotted Woodpecker, has suffered greatly from the loss of riverine forest in many parts of central Europe, although it has, in contrast, increased in the Netherlands and expanded its range in Denmark. Its populations are difficult to monitor, but this species does not seem to be likely to become seriously endangered in the near future.

Competition from other cavity-nesting birds, which take over woodpecker nest-sites, has already been referred to earlier in this section. This pressure can sometimes be heavy enough to place the members of the Picidae at a disadvantage. In those areas from where there are sufficient data, the most serious hole competitor is almost certainly the Common Starling, which has been introduced in many regions, including North America, where it can sometimes usurp a significant proportion of the new cavities made by local woodpeckers (see Breeding). In such situations, and in others where the number of sites suitable for excavation is limited, the provision of artificial snags consisting of hard cylinders filled with styrofoam or polystyrene cylinders

Knowledge of the ecology of threatened picids varies considerably.

The best-studied of all is North America's Red-cockaded Woodpecker, once found across south-eastern USA but now scattered in small and diminishing populations. It requires mature open pine (*Pinus*) forest with a particular structure, produced by regular lightning-induced fires. This site-faithful social picid has not adapted well to the era of commercial forestry, and its conservation status is now Vulnerable. Modern harvesting leaves few of the old, tall trees that the birds need, and forestry companies appear unwilling to implement recovery plans.

[*Picoides borealis*, Talladega National Forest, Alabama, USA.

Adequate monitoring is crucial if limited resources are to be directed to the most threatened species.

The little-studied Helmeted Woodpecker, classified as Vulnerable chiefly because its primary-forest habitat has been extensively cleared and fragmented, may not be so rare as was previously feared. It is a quiet and unobtrusive species, difficult to locate, but individuals and pairs have recently been found in secondary habitats and in degraded forest, as well as in regions from which the species had not been reported for up to 50 years.

The Fernandina's Flicker, while never abundant in Cuba, is now restricted to a handful of areas on the island, with a total population of fewer than 400 pairs. It is not known precisely what has caused the rapid decline, but, as with most woodpeckers, logging and the clearance of natural forests for agriculture have taken their toll. The birds favour palm trees, either in open country or in primary forest, perhaps because they are often invaded by fungus, making the wood softer and more suitable for excavation. With numbers so low and populations so widely scattered, the fortunes of every breeding pair can influence the trend in status. Hurricanes, such as those that hit Cuba in 1996 and 2001, can devastate localized populations, and are capable of extirpating several of them. It will be some time before the effects of the latest hurricane become apparent. Moreover, since these flickers often nest in the same palms as Cuban Amazons (*Amazona leucocephala*), they not infrequently lose their broods to trappers, who topple palm trees in order to collect the young parrots; the flicker's nest is destroyed in the process, and the breeding site is lost forever. Whichever factors have reduced this picid's status from that of a widespread species to its current one of Endangered, the focus of conservation effort is now on Zapata Swamp, a nature reserve which holds almost a third of the remaining population. Even here, however, despite efforts to provide protection, it is proving difficult to police the area effectively.

Many birdwatchers dream of finding an Ivory-billed Woodpecker in the dense bottomland woods of Louisiana, or in the montane pinewoods of Cuba. It is not just its huge size or its sad history that make this picid so famous, for this is a species that had its own public-relations champion. The vivid narrative and photographs of James T. Tanner, who studied some of the last breeding pairs in the USA, evoke wonder of both the bird and its wild forest habitat: "A dramatic reason for the variety in the shape of the forest was age, and its follower, death. Big trees gradually lost their vigor until damage suffered from insects and disease outweighed the yearly growth; then they gradually died, from the top down, until only a rotten trunk stood alone. In so dying, they supplied food for woodpeckers, bare branches for flycatchers to perch upon, and finally let the sun thru to the ground to nurture the bushes, vines and new saplings." Its need for large dead trees hosting wood-boring beetle larvae was the Ivory-bill's undoing; logging and forest clearance ensured that, within a decade, the birds had gone from the Singer Tract of Louisiana, where these photos of birds engaged in breeding were taken during the 1930's. The species survived longer in Cuba, where it was last seen in 1991. How sad that such an enigmatic bird should be lost from the world; and how much sadder that, without urgent action, so many other forest species could easily follow it. The official conservation status of the Ivory-billed Woodpecker is Critical; so, perhaps it is not yet extinct. Following an unconfirmed 1999 report of a pair in Pearl River Wildlife Management Center, in Louisiana, a major expedition in early 2002 may tell us whether this guarded optimism is justified.

[*Campephilus principalis principalis*, Singer Tract, near Tallulah, Louisiana. Photos (digitally coloured for HBW): James T. Tanner]

The world's rarest extant picid, the Critically Endangered Okinawa Woodpecker, inhabits the evergreen forest of the Yamburu Mountains, on the tiny Japanese island of Okinawa. As few as 150 individuals remain, in an area of just 20 km × 30 km. Yet again, deforestation and the developments that follow are the cause of this species' demise. As the lower tree-line advances uphill, ahead of logging, construction, agriculture and the building of golf courses, this reddish-brown picid's numbers have been reduced to a point where disease or typhoons could strike the final blow. Is this a bird which, living in one of the world's richest countries, could yet be saved?

may represent an important measure in managing woodpecker populations. Although these artificial sites have not always produced the hoped-for results, success has often been achieved; further research and refinements should help to make them even more attractive to woodpeckers as nesting sites.

Because many of the Picidae consume large quantities of ants (see Food and Feeding), there is a potential risk of their being subject to secondary poisoning as a result of the spraying with insecticides of important commercial forests. This possibility has not yet been investigated in any detail, but needs to be borne in mind. Correspondingly, woodpeckers which forage in orchards are perhaps vulnerable to the effects of herbicides and pesticides.

Other possible hazards, also alluded to above, include storms, which can destroy large areas of woodland habitat, and fires. In the late 1990's, for example, a major fire which swept through the forest and scrub of the Andean foothills in central Chile effectively destroyed over 6000 ha of the habitat, which was already suffering the effects of a prolonged drought. This region, which forms part of the Central Chile Endemic Bird Area, is at the northern edge of the range of the Magellanic Woodpecker, an uncommon species which is becoming increasingly scarce.

On the whole, woodpeckers are not persecuted by man. On the eastern seaboard of the USA large numbers of migrating Northern Flickers were once killed by gunners in New Jersey and at Cape May, but this practice has, fortunately, now ceased. Nevertheless, the picids can be a nuisance in some areas, where they are therefore considered pests (see Relationship with Man). In parts of the USA, for example, commercial crops are sometimes attacked by some of the frugivorous and nucivorous melanerpinines, and both Red-headed and Lewis's Woodpeckers may be shot as a result of such depredations. In early colonial America, the former of those two was considered a major agricultural pest in orchards and cornfields; a bounty of twopence was paid for each head of that species, and one report tells of over 100 shot from a single cherry tree in one day. Nowadays, this kind of persecution occurs on a far lower scale than was the case in the past, and it seems unlikely to have an adverse effect on the species' total population. Similarly, the damage inflicted by Syrian Woodpeckers on commercial orchards and polyethylene irrigation pipes in parts of the Middle East resulted in large numbers of this woodpecker being shot, but it

had already expanded its range northwards into south-east and central Europe and appears to be thriving in that part of the world. While individual woodpeckers which irritate people by drumming and excavating on houses and other buildings, or which damage utility poles, are still shot on occasion, such actions are generally very localized and do not normally lead to any serious conservation problems.

In summary, it can be said that the Picidae as a family are reasonably secure. Although the two biggest woodpeckers have almost certainly become extinct since about 1990, it is probably fair to add that sufficient knowledge is available to ensure that the vast majority of the remaining 214 species can be conserved. Much remains to be learnt about the ecology and biology of many of them, especially the tiny Neotropical piculets, but at the beginning of the twenty-first century, more than at any other time in man's history, conservationists are aware of the importance of protecting the varied habitats of these and all other wild inhabitants of our shared planet. So long as the political will exists, and the human population does not multiply beyond control, nor engage in large-scale habitat-destroying warfare, there are grounds for cautious optimism.

PLATE 22

## Family PICIDAE (WOODPECKERS) SPECIES ACCOUNTS

### Subfamily JYNGINAE

#### Genus *JYNX* Linnaeus, 1758

##### 1. Eurasian Wryneck

##### *Jynx torquilla*

**French:** Torcol fourmilier **German:** Wendehals **Spanish:** Torcecuello Euroasiático  
**Other common names:** (Northern) Wryneck

**Taxonomy.** *Jynx Torquilla* Linnaeus, 1758, Europe = Sweden. Forms a superspecies with *J. ruficollis*. Several additional races described from Asia, but geographical variation largely clinal, also somewhat random, and individual variation notable, with much overlap in characters, and all are considered better lumped with nominate race: birds breeding from Ural Mts to Yenisey named as *sarudnyi* on basis of paler plumage with fewer markings below, and others farther E and in China as race *chinensis* on basis of more barred plumage, but both populations contain individuals closely resembling or identical to W birds; Japanese birds described as *japonica*, more barred and with more rufous in plumage, but some are identical to W (including European) breeders. Four subspecies recognized.

##### **Subspecies and Distribution.**

*J. t. torquilla* Linnaeus, 1758 - most of Eurasia, except parts of S; winters in Africa and S Asia.  
*J. t. ischusii* Kleinschmidt, 1907 - Corsica, Sardinia, Italy and E Adriatic coast; winters in Africa.  
*J. t. mauretanica* Rothschild, 1909 - NW Africa.  
*J. t. himalayana* Vaurie, 1959 - NW Himalayas (N Pakistan E to Himachal Pradesh); winters to S, at lower altitudes.

**Descriptive notes.** 16-17 cm; c. 30-50 g. Small, aberrant, long-tailed woodpecker with short, pointed bill very narrow across nostrils. Both sexes have forehead to hindneck pale grey, speckled darker, finely barred black and rufous, with tiny white feather tips (white spots and black bars usually more distinct on crown); narrow creamy stripe from nostril to below eye; thin creamy supercilium, broad rufous-mottled black band from eye through upper ear-coverts and irregularly down neck side; buff to cinnamon-buff stripe from bill base to lower ear-coverts and neck side, usually finely barred dark; upperparts pale grey, finely dark-speck-

led and with narrow dark shaft streaks, feathers sometimes with black, rufous and whitish marks at tips; central mantle black, edged rufous, this pattern often continuing as irregular band up to crown centre; outer scapulars black, large pale buffish spot at tip; wing-coverts and tertials brownish-buff, speckled grey and rufous-buff, thin black shaft streaks, black subterminal bars, creamy tips; primaries and secondaries dark brown with rufous-buff spot-bars; tail with usually 4-5 (variable) irregular, thin black bars often bordered by grey and buff bands; chin whitish, throat and upper breast buff or cinnamon-buff, all narrowly vermiculated black, often incomplete dark malar stripe; rest of underparts whitish with variable cream or buff suffusion, narrow dark bars on breast, arrowhead marks on lower underparts (extent of markings variable, belly often plain); underwing barred grey and white, coverts buff with black bars; bill dark horn-brown, often tinged green; iris brown to red-brown; legs brownish to grey-green, occasionally tinged yellow or pink. Differs from *J. ruficollis* in lack of rufous on throat and breast, more barred than streaked flanks. Juvenile like adult, but duller, darker, more barred (less streaked) above, more clearly barred below, fewer but more pronounced tail bars, outer primary much longer. Race *ischusii* is darker than nominate, has dark patch on upperparts more prominent, markings below heavier, shorter wings more rounded; *mauretanica* similar but slightly smaller, paler below; *himalayana* is much more strongly barred below, including belly. Voice. Song slightly ascending series of 8-15 "kwia" notes, sometimes raucous, similar to call of small falcon (*Falco*), by single bird or both of pair simultaneously; low, guttural notes during close contacts between mates; long wavering series of "tak" notes in alarm; hissing notes by nestlings in defence.

**Habitat.** Open forest, clearings, woodland with low undergrowth, wooded pasture, and unimproved meadowland with scattered trees, so long as dry and sunlit, and grass areas not too well developed; avoids damper vegetation and higher mountains. Prefers open riparian forest, and lighter parts of more closed mixed or deciduous broadleaf forest and forest edge; also copses, avenues, plantations, parks, orchards, larger gardens, non-intensive farmland; locally, also pure stands of pine (*Pinus*) or larch (*Larix*). In non-breeding season, open dry woodland, bushy grassland and gardens, in S Asia typically in scrub, thickets, also in canopy of forest and in cultivations; overwinterers in S Europe found mostly in coastal wetlands and *maquis*. Migrants also in treeless open habitats, including desert. Mostly lowlands to c. 1000 m, occasionally higher, in Europe to 1600 m in Alps and Caucasus; in Himalayas, breeds at 1500-3300 m; non-breeders to 1800 m in SE Asia.

**Food and Feeding.** Diet mostly ants, mainly larvae and pupae; other insects include e.g. small beetles, aphids (Aphididae), Lepidoptera, dipteran flies, bugs (Hemiptera). Some spiders taken, also woodlice (Isopoda); occasionally molluscs, frog tadpoles (*Rana*), bird eggs; rarely, plant matter (berries). In Europe, the ant genera *Lasius* and *Tetramorium* especially important; in studies of 7 broods in 2 areas of Switzerland, using photography at nest, *Lasius*, *Formica*, *Tetramorium*, *Tapinoma* and *Myrmica* were brought to nestlings, and ants recorded in 95% of feeds. On non-breeding grounds, genera *Crematogaster* and *Camponotus* are typical prey. Forages mainly on the ground, occasionally in trees. Procures prey from crevices or from the surface; uses bill to open anthills. Hops on ground and along horizontal or sloping branches.

**Breeding.** Lays in May-Jun; in S of range, second clutch sometimes laid in Jun, rarely Jul, occasionally third brood attempted. Territorial; home range large at start of breeding season, shrinking considerably after pairing; sings on exposed perch or from prospective nest-hole. On meeting, partners display by head-swinging with ruffled head feathers; courtship feeding may extend into

incubation period. Nest-site selected by both sexes, in natural cavity, in old hole of another woodpecker, or in artificial nestbox, at height of 1-15 m; occasionally in building in China; cavity cleaned out over several days, removes any eggs or chicks of other hole-nester. Clutch 7-12 eggs, sometimes far fewer, but clutches of 18-23 eggs are product of more than one female; incubation by both adults, average period c. 11-12 days; nestlings fed by both parents, respond to intruders with characteristic snake-like head movements and hissing, fledge after 20-22 days, independent 1-2 weeks later. Breeding success good; fledging rate over 70%; productivity 3-4 young per pair. First breeds at 1 year. Longevity generally 2-10 years.

**Movements.** Largely migratory. European and W Asian populations move to W, C & E Africa, E populations to mainly N & C Indian Subcontinent and SE Asia; migrates mainly at night, can cover 600 km in 8 days. Leaves Europe in late summer, sometimes as early as Jul; some Scandinavian birds wander through Britain; otherwise, passage on broad front through C Europe mid-Aug to end Sept, crossing Alps, and then Iberia or the Balkans, reaching African winter quarters from late Aug and early Sept; birds from E Europe and W Asia probably move through Turkey and Arabian Peninsula, with peak in Caucasus mid-Aug, in C Anatolia end Sept or early Oct; present in E Africa Oct-Apr. Returns N begins Jan-Mar, reaching C European breeding grounds early Apr, Russia and Mongolia late Apr to early May, and N Europe by mid-May. Some individuals of nominate race winter in Mediterranean region and in SE Iran; Mediterranean race *tschusii* and N African *mauretanica* migrate short distances, or make only altitudinal movements. In E Asia, migrants pass through Korea in Sept, and in Apr-May; non-breeders present early Sept to end Apr in N India, Oct-Apr in Myanmar. Straggles occasionally to W Alaska.

**Status and Conservation.** Not globally threatened. European population estimated at c. 382,000 pairs, of which most in E, including c. 158,000 in Russia; 45,000 in Spain, probably 5000-10,000 in Sweden, c. 4000 in Finland. Densities vary widely, in Europe decreasing from E to W & S and with preference for continental climate over maritime one, e.g. 1 pair/2-5 km<sup>2</sup> in Russia and Belarus but less than 1 pair/50 km<sup>2</sup> in Denmark, Netherlands, Greece and Portugal; in E Europe, densities in optimal habitats can be high, with inter-nest distances of only 40-50 m, even 20 m. In NW Himalayas, scarce to locally common; uncommon in N Pakistan, frequent in Kashmir. In W & C Europe, long-term decline since mid-19th century, with considerable reduction in range and numbers during 20th century; disappeared from N France and from parts of Belgium, Netherlands and Germany after 1960's; rapid decline in Britain, where almost extinct by 1990's; numbers in Finland and Sweden decreased by over 50% in latter decades of 20th century. Decline possibly initiated by climatic changes, with increase in rainfall during breeding season; since 1950's, various other factors, including loss of important habitats such as orchards and unimproved meadows, replacement of hardwoods with conifers, and intensive farming practices accompanied by large-scale pesticide and herbicide usage, are likely major causes of acceleration of the decline; reduction of ant populations almost certainly a further significant factor.

## 2. Rufous-necked Wryneck

### *Jynx ruficollis*

**French:** Torcol à gorge rousse **German:** Rotkehl-Wendehals **Spanish:** Torcecuello Africano  
**Other common names:** Rufous-breasted/Red-breasted Wryneck, Rufous-throated/Red-throated Wryneck, African Wryneck

**Taxonomy.** *Jynx ruficollis* Wagler, 1830, Uitenhage, eastern Cape Province, South Africa.

Forms a superspecies with *J. torquilla*. Cameroon birds formerly separated as race *thorbeckei* on basis of more completely barred throat, but this feature occurs also in E populations of *pulchricollis*. Birds from N Angola sometimes separated as race *pectoralis*, but indistinguishable from nominate; proposed race *cosensi* (Kenya, Tanzania) now considered synonymous with nominate. Three subspecies recognized.

**Subspecies and Distribution.**

*J. r. aequatorialis* Rüppell, 1842 - Ethiopia.

*J. r. pulchricollis* Hartlaub, 1884 - SE Nigeria and Cameroon to NW Zaire, S Sudan and NW Uganda.

*J. r. ruficollis* Wagler, 1830 - SE Gabon to SW & E Uganda, SW Kenya and extreme N Tanzania, and S to N & E Angola (S to Cuanza Norte and Malanje, E to Moxico), NW Zambia and E South Africa.

**Descriptive notes.** 19 cm; male 52-59 g, female 46-52 g. Small, aberrant, long-tailed woodpecker with short, pointed bill. Both sexes have lores and ear-coverts barred buff-white and brown, malar area whitish with brown vermiculations; forehead to uppertail-coverts, including scapulars, wing-coverts and tertials, grey-brown, variably marked with black shaft streaks/bars and subterminal spots, wing-coverts with white tips; irregular central black stripe from crown centre to mantle; crown sides, rump, uppertail-coverts, wing-coverts and tertials usually very finely vermiculated; flight-feathers dark brown,

barred light rusty to rufous-white; uppertail brownish-grey with prominent white-bordered black bars; chin to upper breast rufous-chestnut (extent of colour somewhat variable), central throat occasionally barred (e.g. in Kenya); rest of underparts whitish with brown shaft streaks, flanks and lower belly to vent tinged buffy, lower flanks also barred, undertail-coverts barred; underwing barred brown and pale rufous-buff; bill brownish-grey, darker tip; iris brown; legs olive-green to brownish. Differs from *J. ruficollis* in larger size, rufous breast or throat, more streaked and less barred belly, much longer outer primary. Juvenile darker with more barring above, most of underparts finely barred, rufous colour duller and less extensive. Races differ mainly in tone of upperparts and in amount and darkness of rufous below, but much variation: *aequatorialis* has rufous reaching lower breast, and often upper flanks, also extensive rufous-buff on lower flanks to lower belly and undertail-coverts, ventral streaking less prominent, sometimes some barring on throat; *pulchricollis* is less grey-brown above, more rufous-tinged, throat to breast chestnut rather than rufous, throat more strongly barred and sometimes without rufous, flanks washed rusty, chestnut on lower belly to undertail-coverts. Voice. Sings from dead tree, loud, high "kwik-kwik-kwik-kwik-kwik-kwik, kwee kwee kwee" or "week-week-week-week" series by male, lower-pitched "uit-uit-uit-uit-uit" by female; also low, guttural "peegeh-peegeh-peegeh"; long series of "krok" notes in display; quiet "klik" calls in alarm.

**Habitat.** Inhabits wooded grassland, open forest and forest edge, as well as open areas with trees. Widespread in drier acacia (*Acacia*) savanna and open bush, especially in wooded gorges on hillsides and along streams; occurs in miombo woodland, also in denser *Cryptosepalum* woodland in E Angola; also found in plantations, gardens, and stands of exotic trees in urban areas. Occurs from 600 m up to 3000 m, in Kenya mostly 1400-2500 m; recorded up to 1550 m in S Africa.

**Food and Feeding.** Mainly ants and their pupae and eggs; also some other small arthropods. Gleans items from the bark of dead branches of trees, also from larger bushes; also forages frequently on ground, where it hops about with tail raised.

**Breeding.** Apr in Gabon; in Angola, adult in breeding condition in Aug, juvenile seen in Sept; breeds Aug-Dec in South Africa; often two broods reared in a season, but sometimes even three or four. Courtship feeding by male sometimes continues into incubation period. Nest situated in disused hole of barbet (Capitonidae) or woodpecker, or in natural crevice in trunk or bough of tree; sometimes uses artificial nestbox, hollow fence post, or hole under eaves of a house. Clutch 3 or 4 eggs, with exceptional extremes 1-6; both sexes incubate, period 12-15 days; both care for chicks, which give snake-like head movements and hissing sounds in response to intruders; fledging period 25-26 days. One pair was recorded raising three successive broods, with 14-24 days between fledging of one brood and laying of next clutch. Nests regularly parasitized by honeyguides (Indicatoridae).

**Movements.** Largely resident, but dispersive, and perhaps somewhat nomadic. Movements not well understood; records outside known breeding areas, particularly in E (including Mozambique), may represent post-breeding dispersal or, possibly, short-distance migration. At least partially migratory in S parts of range; migrants pass through NE South Africa in Feb and Mar; some S African birds migrate as far N as E Zaire. Often colonizes an area for a period and then vanishes, only to reappear several years later; also breeds, at least occasionally, in regions outside normal breeding areas.

**Status and Conservation.** Not globally threatened. Locally common, but often irregular in occurrence. Not uncommon in Angola; uncommon in Ethiopia; uncommon in Kenya; locally common in South Africa, where appears to have expanded considerably due to introduction of alien trees to many grassland areas which formerly lacked trees. Shows a rather disjunct breeding range, and presence in many areas is rather erratic; breeds at least occasionally in regions outside normal range; pairs are usually widely scattered, and there are considerable annual fluctuations in numbers, making assessment of population size difficult. Occurs in many protected areas throughout range.

**Bibliography.** Bannerman (1953), Bennun & Njoroge (1996), Benson (1981), Benson & Benson (1977), Benson *et al.* (1971), Bowen (1983), Brown & Britton (1980), Cheeseman & Sclater (1935), Clancey (1987), Dean (2000), Demey *et al.* (2000), Deshayes (1969), Dowsett (1982, 1989b), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Farnsworth *et al.* (2000), Friedmann (1930a), Fry *et al.* (1988), Ginn *et al.* (1989), Harrison *et al.* (1997), Hustler *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981b), Mackworth-Præd & Grant (1957, 1962, 1970), Maclean (1993), Newman (1996), Nikolaus (1987), Pinto (1983), Sargeant (1993), Short (1980, 1985b), Short & Bock (1972), Short *et al.* (1990), Sinclair (1987), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Sinclair & Whyte (1991), Sinclair *et al.* (1993), Snow (1978), Storer & Dalquest (1967), Tarboton (1976, 2001), Urban & Brown (1971), Zimmerman *et al.* (1996).

## Subfamily PICUMNINAE

### Tribe PICUMNINI

#### Genus *PICUMNUS* Temminck, 1825

### 3. Speckled Piculet

#### *Picumnus innominatus*

**French:** Picumne tacheté **German:** Tüpfelzwergspecht **Spanish:** Carpinterito Moteado  
**Other common names:** Spotted Piculet(!)

**Taxonomy.** *Picumnus innominatus* Burton, 1836, Sikkim.

Despite enormous geographical separation, present species appears to be closely related to congeners (see page 300). Proposed races *simlaensis* (NW Himalayas) and *avanculorum* (SW India) now considered synonymous with, respectively, nominate and race *malayorum*. Three subspecies currently recognized.

#### **Subspecies and Distribution.**

*P. i. innominatus* Burton, 1836 - NE Afghanistan, N Pakistan and Kashmir E through N India and Nepal to SE Tibet and Assam.

*P. i. malayorum* Hartert, 1912 - peninsular and NE India (except Assam) E to SW China (S Yunnan), S to Indochina, Sumatra and N Borneo.

*P. i. chinensis* (Hargitt, 1881) - C, E & S China (S from Sichuan and S Jiangsu).

**Descriptive notes.** 10 cm; 9-13.2 g. Male has rufous-orange to yellow forehead barred or spotted black, yellowish-white lores; broad black stripe from eye backwards, bordered by white stripes, black malar stripe with white feather fringes; olive-green crown, bright olive-green upperparts; upperwing and coverts brownish-black with greenish or yellow-green edges; black uppertail, inner webs of central feather pair and subterminal patches of outer 2 pairs white; dull white chin and throat, yellowish lower throat usually with few black spots; remaining underparts white to pale yellowish-white with black spots, flanks more barred, belly and central undertail-coverts usually unmarked; underwing grey, coverts tinged yellow and spotted black; bill short, culmen slightly curved, black or bluish-black; iris brown, blue-grey orbital skin; legs blue-grey. Female as male, but forehead olive-green. Juvenile as female, but plumage duller, bill paler. Race *malayorum* is slightly smaller and duller, with darker, greyer crown, heavier spotting below; *chinensis* is slightly larger, with cinnamon-brown crown and upper mantle, black facial markings brown-tinged, whiter lores, coarser markings below. VOICE. High "ti-ti-ti-ti" by male as advertising or territorial call; frequently a high-pitched squeaky "sik-sik-sik"; occasional sharp "tsick" or "tsit"; drums loudly.

**Habitat.** Deciduous and mixed deciduous forest, evergreen tropical montane forest, also open second growth, particularly where bamboo present. Mostly in foothills or lower hills, locally higher or lower: 900-1830 m in Nepal and Sikkim, up to 2400 m in NE India and to 3000 m in NW Himalayas; c. 900-1400 m in Peninsular Malaysia; down to 100 m, and even to sea-level, in Sumatra and Borneo.

**Food and Feeding.** Diet consists of insects and their larvae, especially ants, but also geometrid caterpillars, weevils (Curculionidae) and longhorn beetles (Cerambycidae); also takes spiders and their eggs. Hunts singly or in pairs; often present in mixed-species flocks, though in general only outside breeding season. Forages in undergrowth, on trunk and branches of small trees, and in bushes, vines and bamboo; frequently hangs upside-down, and moves along thin vertical twigs; often concentrates on one spot for several minutes, pecking and hammering vigorously; presence often revealed by loud persistent tapping. Also hovers to catch prey, or pursues flushed prey to take it on the wing.

**Breeding.** Jan-May. Male displays by circling around mate and pursuing her around branch. Nest excavated by both sexes, at 1-5 m, occasionally as low as 0.3 m, in dead branch or small tree, or bamboo, occasionally in palm fronds; hole entrance c. 2.5 cm across. Clutch 2-4 eggs; both parents incubate, period 11 days; both also feed nestlings, which fledge after 11 days; young disperse soon after leaving nest.

#### **Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common or fairly common throughout much of range; generally uncommon in peninsular India; uncommon in China. Has been considered local and very rare in most of NW part of range, but recent observations in N Pakistan suggest small population at low density in Margalla Hills and other sightings there indicate that species is probably uncommon to scarce, and possibly overlooked. Status in Borneo uncertain; specimens known only from N Sabah, but this species may possibly be present elsewhere. Occurs in several protected areas within its range, including Thattakad Bird Sanctuary in Kerala and Namdapha National Park in Arunachal Pradesh (India), and Nam Nao and Doi Inthanon National Parks (Thailand).

**Bibliography.** Ali (1969, 1996), Ali & Ripley (1983), Ali *et al.* (1996), Andrew (1992), Bangs & Van Tyne (1931), Benstead *et al.* (1997), Betts (1934), Champion-Jones (1938), Chasen & Hoogerwerf (1941), Deignan (1945), Eames & Robson (1992), Etchécopar & Hue (1978), Gandy *et al.* (1998), Grimmer *et al.* (1998), Harvey (1990), Hue & Etchécopar (1970), Inskipp & Inskipp (1991), Jeyarajasingam & Pearson (1999), Law (1948), Lekagul & Round (1991), Leven (1998), Li, Yanjuan (1962), Ludlow (1937, 1944), MacKinnon & Philipps (1993, 2000), Madoc (1976), van Marle & Voous (1988), Medway & Wells (1976), Osmaston (1902), Paludan (1959), Raja *et al.* (1999), Riley (1938), Ripley (1982), Roberts (1991), Robson (2000), Shankar Raman (2001), Short (1973d), Smythies (1986, 1999), Stepanyan (1995), Storrs-Fox (1937), Tymstra *et al.* (1997), Vowles & Vowles (1997), Wells (1985, 1999), Zhao Zhengjie (1995).

### 4. Bar-breasted Piculet

#### *Picumnus aurifrons*

**French:** Picumne barré **German:** Goldstirn-Zwergspecht **Spanish:** Carpinterito del Amazonas  
**Other common names:** Gold-fronted/Golden-fronted Piculet (yellow-crowned rices)

**Taxonomy.** *Picumnus aurifrons* Pelzelin, 1870, Engenho do Gama, Caiçara and Salto do Girao, west-central Brazil.

May be more closely related to *P. fuscus*. Races *juruanus* and *borbae*, with red forehead streaks, sometimes treated as forming a separate species "*P. borbae*", although from a biogeographical standpoint there are major objections. Seven subspecies currently recognized.

#### **Subspecies and Distribution.**

*P. a. flavifrons* Hargitt, 1889 - NE Peru and W Brazil (along R Solimões).

*P. a. juruanus* Gyldenstolpe, 1941 - E Peru to W Brazil (upper R Juruá).

*P. a. purusianus* Todd, 1946 - W Brazil (upper R Purus).

*P. a. wallacii* Hargitt, 1889 - middle and lower R Purus E to lower R Madeira.

*P. a. borbae* Pelzelin, 1870 - lower R Madeira E to lower R Tapajós.

*P. a. transfasciatus* Hellmayr & Gyldenstolpe, 1937 - R Tapajós E to R Tocantins.

*P. a. aurifrons* Pelzelin, 1870 - N Mato Grosso from upper R Madeira E to upper R Tapajós.

**Descriptive notes.** 7.5 cm; 8-10 g, male 9-2 g, female 8-6 g. Male has top of head black, yellow streaks mostly on forehead, remainder spotted white; buff lores, grey-brown cheeks and ear-coverts, whitish line behind eye; olive-green upperparts, somewhat browner wing-coverts and tertials with paler greenish edgings; brownish-black primaries and secondaries, edged greenish-yellow; black uppertail, central feather pair with yellowish-white inner webs, outer 2 pairs with whitish subterminal patch; whitish chin and throat weakly barred dark at sides; remaining underparts pale yellowish-white, breast barred brown, breast sides

and upper belly with arrowhead-shaped streaks, belly and flanks broadly streaked brown; underwing-coverts yellowish; bill short, grey to blue-grey; iris brown, orbital skin grey; legs greyish. Differs from similar *P. lafresnayi* in yellow forehead streaks, unbarred back, streaked belly. Female has entire forehead and crown spotted white. Juvenile duller brown, crown browner and streaked (not spotted), markings below less heavy, streaks extending up to lower breast. Race *purusianus* is darker above, breast more heavily barred black; *flavifrons* similar but faintly barred above, breast barring less heavy, belly strongly spotted; *wallacii* is obscurely barred above, paler below, breast bars fainter, belly more spotted; *transfasciatus* has heavily barred upperparts, strongly barred breast; *borbae* has red forehead streaks, yellower tertial edges, yellower belly, stronger blacker breast bars; *juruanus* also has reddish-orange forehead streaks, but far weaker breast barring. VOICE. Call "tsirrit-tsit-tsit", resembling that of hummingbird (Trochilidae).

**Habitat.** Inhabits humid tropical *terra firme* forest, and also seasonally inundated *várzea* forest; found mainly at edges and in clearings, and also in second growth. Recorded from lowlands up to 1100 m.

**Food and Feeding.** Virtually unknown; presumably insects. Seems to prefer the upper canopy for foraging.

**Breeding.** Season presumably Jun-Nov. No other information.

**Movements.** Apparently resident.

**Status and Conservation.** Not globally threatened. Very poorly known. Appears to be at best uncommon, but possibly overlooked. Occurs in Manu National Park and Tambopata Reserve, both in Peru.

**Bibliography.** Angehr & Aucca (1997), Clements & Shany (2001), Donahue (1994), Dubs (1992), Meyer de Schauensee (1982), Olrog (1968), Oren & Parker (1997), Remsen & Traylor (1989), Ruschi (1979), Sick (1993), da Silva (1996), da Silva *et al.* (1990), Sneath (1914), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Wheatley (1994).

### 5. Orinoco Piculet

#### *Picumnus pumilus*

**French:** Picumne de l'Orénoque **Spanish:** Carpinterito del Orinoco  
**German:** Orinokozwergspecht

**Taxonomy.** *Picumnus pumilus* Cabanis & Heine, 1863, no locality.

Forms a superspecies with *P. lafresnayi*. Often considered conspecific, but no evidence of interbreeding where ranges overlap slightly in SE Colombia; probably separated ecologically. Monotypic.

**Distribution.** E Colombia, S Venezuela (S Amazonas) and NW Brazil (R Uaupés E to R Jaú).

**Descriptive notes.** 9 cm; 9-10 g. Male has dark brown cap with small yellow forecrown spots, whiter spots on rest of crown; pale buff lores, blackish ear-coverts with variable white spots, white line behind eye; brownish-green upperparts; wing-coverts and tertials sometimes browner, with yellowish-green edgings; primaries and secondaries brown, edged and tipped greenish; black uppertail, central feather pair with white inner webs, outer 3 pairs with white subterminal patch; pale yellowish to buff-white underparts barred dark brown, belly centre usually unbarred; underwing grey-brown, dark-barred yellower cov-

erts; bill short, culmen slightly curved, blackish with paler base; iris brown to grey-brown, orbital skin grey to blue-grey; legs grey. Differs from *P. lafresnayi* in slightly smaller size, yellow rather

than red forehead streaks, darker unbarred upperparts, darker ear-coverts. Female has white forecrown spots. Juvenile greener above, forehead and crown streaked or spotted buff, less prominently marked below. Voice. Undescribed.

**Habitat.** Humid forest; recorded from edge of gallery forest and in dense thickets. Lowlands to 300 m, locally to 500 m.

**Food and Feeding.** No information; presumably ants and similar small insects. Forages from lower levels up to the canopy.

**Breeding.** Not recorded; season likely to be Nov-Dec.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Orinoco-Negro White-sand Forests EBA. Poorly known and probably uncommon. Present in Jaú National Park, in Brazil.

**Bibliography.** Hilty & Brown (1986), Meyer de Schauensee (1982), Olrog (1968), Rodner *et al.* (2000), Ruschi (1979), Sick (1993), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

## 6. Lafresnaye's Piculet

### *Picumnus lafresnayi*

**French:** Picumne de Lafresnaye **Spanish:** Carpinterito de Lafresnaye  
**German:** Lafresnaye-Zwergspecht

**Taxonomy.** *Picumnus Lafresnayi* Malherbe, 1862, Ecuador.

Forms a superspecies with *P. pusillus*; these two are sometimes considered conspecific, but their ranges overlap slightly in SE Colombia apparently without interbreeding. Four subspecies recognized.

**Subspecies and Distribution.**

*P. l. lafresnayi* Malherbe, 1862 - SE Colombia, E Ecuador and N Peru.

*P. l. pusillus* Pinto, 1936 - NC Brazil on middle R Amazon E to R Negro.

*P. l. taczanowskii* Domaniewski, 1925 - NE & NC Peru (S to Huánuco).

*P. l. punctifrons* Taczanowski, 1886 - E Peru.

**Descriptive notes.** 9-10 cm; 9-10 g. Male has dark olive-brown cap with red forecrown spots, whitish spots on rest of crown and nape; pale buff lores, whitish feather edges forming pale stripe behind eye, greyish-buff ear-coverts streaked or spotted brown; dark green or brownish-green upperparts barred yellowish-green; upperwing and its coverts greenish-brown with yellowish edgings, primaries browner; uppertail blackish, central feather pair with broad white stripe on inner webs, outer 3 pairs with large area of white towards tip; buffish-white chin and throat with narrow black feather edges; rest of underparts pale yellowish-white with broad black bars, bars broadest on lower areas, occasionally broken in belly centre; underwing brownish with dark-barred yellowish-white coverts; bill short, culmen curved, black with grey base; iris brown to brown-grey, orbital skin greyish; legs grey. Differs from *P. pusillus* in larger size, barred and brighter upperparts, red forehead spots, paler ear-coverts. Female has white forecrown spots. Juvenile duller, with greener upperparts, less evenly barred below. Races other than nominate differ in having yellow-orange forecrown spots, and less heavily barred upperparts: *punctifrons* has slightly larger bill, darker ear-coverts, narrower bars below; *taczanowskii* has blacker crown, and broader, more irregular dark barring below; *pusillus* has upperparts slightly rufous-tinged, narrow dark bars below, centre of belly more or less unbarred. Voice. Largely silent, but occasional high-pitched "tseeey, tsit".

**Habitat.** Inhabits heavily forested, very humid country, preferring secondary growth, forest edges and clearings. Occurs in lowlands and foothills up to 1400 m; occasionally found up to 1800 m in Ecuador.

**Food and Feeding.** Termites; presumably also other small invertebrates. Forages in lower and middle strata. Gleaning is the only feeding technique recorded. Often accompanies mixed-species feeding flocks.

**Breeding.** Few records available suggest nesting in Jul-Nov. One nest was in hole c. 3 m up in a shrub, and contained 2 eggs; both sexes care for the brood, and once an additional full-grown female observed to roost with the eggs; incubation and fledging periods undocumented.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common in Ecuador; regularly recorded on Baeza-Tena and Loreto roads. Considered rare in Peru.

**Bibliography.** Balchin & Toyne (1998), Bloch *et al.* (1991), Clements & Shany (2001), Hilty & Brown (1986), Peres & Whitaker (1991), Ridgely & Greenfield (2001), Ridgely *et al.* (1998), Rodner *et al.* (2000), Salaman *et al.* (1999), Sick (1993), Stotz *et al.* (1996), Wheatley (1994), Williams & Tobias (1994), Zimmer (1930).

## 7. Golden-spangled Piculet

### *Picumnus exilis*

**French:** Picumne de Buffon **Spanish:** Carpinterito Telegrafista  
**German:** Goldschuppen-Zwergspecht

**Taxonomy.** *Picus exilis* M. H. K. Lichtenstein, 1823, São Paulo; error = Bahia.

May be more closely related to *P. fuscus*. Formerly treated by many authors as conspecific with *P. nigropunctatus*, which was included as a synonym of the form "*salvini*"; latter, described from "Bogotá" skins with no type locality, had earlier been lumped as a race of present species; all pre-1990's taxonomic conclusions were, however, based on totally inadequate material, with very few study skins available, and recent research using series of specimens has shown "*salvini*" to be almost certainly a synonym of *P. squamulatus obsolatus*. Six subspecies recognized.

**Subspecies and Distribution.**

*P. e. undulatus* Hargitt, 1889 - extreme E Colombia (NE Guainía), SE Venezuela, N Brazil (Roraima) and W Guyana.

*P. e. clarus* J. T. Zimmer & Phelps, Sr., 1946 - E Venezuela in E Bolívar and S Delta Amacuro.

*P. e. buffini* Lafresnaye, 1845 - E Guyana E to NC Brazil (Amapá).

*P. e. alegriae* Hellmayr, 1929 - coastal NE Pará and NW Maranhão (NC Brazil).

*P. e. pernambucensis* J. T. Zimmer, 1947 - coasts of Pernambuco and Alagoas (NE Brazil).

*P. e. exilis* (M. H. K. Lichtenstein, 1823) - coastal Bahia S to Espírito Santo (EC Brazil).

**Descriptive notes.** 9-10 cm; 8.5-10 g. Male has black forehead to hindneck, feathers of forecrown tipped red, those of mid-crown to hindneck tipped white; buffish-white lores, white line behind eye; yellowish-white cheeks and ear-coverts with dark feather edges; olive-green upperparts with darker feather centres, broad yellow-green edgings; wing-coverts olive-green, narrowly edged white, with black-edged white tips; brownish-green flight-feathers edged yellow-green, tertials broadly edged and with black submarginal lines; dark brown uppertail, central feather pair with broad white stripe on inner webs, outer 3 pairs with

large white subterminal mark on outer webs; pale yellowish-white malar, chin and throat, barred blackish; rest of underparts pale yellowish, barred blackish, bars broken and more spot-like on belly; brown and white underwing with whitish coverts; bill short, pointed, culmen curved, black upper mandible, silvery-based lower mandible; iris yellow to dark brown, orbital skin greyish; legs greyish, sometimes tinged green or blue. Differs from *P. nigropunctatus* in yellower upperparts, yellower underparts with bars rather than spots. Female has entire top of head white-spotted. Juvenile duller, crown olive or greyish with off-white streaking, markings above and below more diffuse and irregular. Race *undulatus* is slightly larger, more olive-brown to yellowish-olive with large blackish feather centres above, wing-coverts less obviously pale-tipped, paler and broadly dark-barred below; *clarus* is slightly yellower above and has broken narrower barring below than previous; *buffini* has distinctive black-bordered white spots at feather tips above; *alegriae* is rather dull, more olive above, whiter below; *pernambucensis* has more olive upperparts, more evenly barred underparts. Voice. Described as "tsilit, tsitrrr".

**Habitat.** Rainforest and cloudforest, second growth, disturbed forest; also dense growth with bamboo along rivers, mangroves; also open woodland and savanna edge in the sandy belt. Lowlands, to 1900 m in areas with tepuis.

**Food and Feeding.** Ants are the only kind of food documented. Species forages inconspicuously, alone or in pairs; also joins mixed-species flocks. Pecks and hammers on small branches in lower strata of forest, at 1-5 m; moves about in manner similar to that of a tit (Paridae), often hanging on thin twigs.

**Breeding.** Dec-Mar in Venezuela and Surinam. Nest excavated in branch or stump with soft wood. No other information available.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. A very poorly known species; no data available on numbers; possibly at best uncommon. Occurs in Parque Estadual da Pedra Talhada in Brazil, and in Imataca Forest Reserve and El Dorado in Venezuela. Since this piculet is often found in more open habitats, including disturbed forest, human activities may possibly lead to its range being expanded.

**Bibliography.** Chapman (1931), Cohn-Haft *et al.* (1997), Haverschmidt & Mees (1994), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Parker & Goerck (1997), Pinto & Camargo (1961), Reynaud (1998), Rodner *et al.* (2000), Ruschi (1979), Sick (1993), Snyder (1966), Stotz *et al.* (1996), Thiollay & Jullien (1998), Tostain *et al.* (1992), Wheatley (1994).

## 8. Black-spotted Piculet

### *Picumnus nigropunctatus*

**French:** Picumne maculé **Spanish:** Carpinterito Punteado  
**German:** Schwarzflecken-Zwergspecht  
**Other common names:** Black-dotted Piculet

**Taxonomy.** *Picumnus nigropunctatus* J. T. Zimmer & Phelps, Sr., 1950, Araguaímujo Mission, Orinoco Delta, Venezuela.

Sometimes treated as conspecific with *P. spilogaster*, but vocalizations differ. Although initially described as a full species, was later lumped in *P. exilis* as a synonym of form "*salvini*"; however, latter shown by recent research to be almost certainly a synonym of the taxon *P. squamulatus obsolatus*, from which present species differs significantly in plumage details. Further research needed on relationships. Monotypic.

**Distribution.** NE Venezuela, from N & E Sucre to NE Monagas and Delta Amacuro (S to R Orinoco).

**Descriptive notes.** 9 cm. Male has top of head black, forecrown feathers tipped scarlet-red, rest spotted white; buff-white lower forehead and lores, whitish line behind eye; buffish ear-coverts broadly dark-edged; brownish upperparts with greenish-yellow edgings, mantle feathers with oval-shaped dark brown centre and usually whitish subterminal spot, uppertail-coverts yellower; darker brown wings, coverts with paler edges tending towards white or with indistinct white subterminal spots, secondaries and tertials broadly edged yellow to whitish; black uppertail, central feather pair with broad white or yellow-white stripe on inner webs, outer 2 pairs with large yellowish-white stripe across outer webs; yellowish-white malar, chin and throat with thin dark tips; rest of underparts straw-yellow, breast with broad large black spots, flanks and belly sides with slightly elongated spots; underwing brownish, coverts buff; bill black with whitish-grey base; iris dark brown, orbital ring dark blue-grey; legs greenish-grey. Differs from all other Neotropical *Picumnus* in having large black spots on breast, as well as on belly sides and flanks. Female has forecrown spotted white. Juvenile apparently undescribed, presumably duller and more barred. Voice. 2-4 high, thin "seet" notes, rather halting and well separated.

**Habitat.** Humid lowland tropical forest, including *várzea* and *terra firme*, mainly at forest edges; also second growth. In Caño Colorado (Monagas), common at forest borders and present in all other habitats (humid forest, woodland edge). Rarely occurs much above sea-level.

**Food and Feeding.** No documented information.

**Breeding.** Apparently not recorded.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common at Caño Colorado, where up to 15 individuals have been recorded per day during dry season.

**Bibliography.** Boesman (1995), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Rodner *et al.* (2000).

9. Ecuadorian Piculet

Picumnus sclateri

**French:** Picumne de Sclater    **German:** Braunoehr-Zwergspecht    **Spanish:** Carpinterito Ecuatoriano

**Taxonomy.** *Picumnus sclateri* Taczanowski, 1877, Lechugal, Peru. Three subspecies recognized.  
**Subspecies and Distribution.**  
*P. s. parvistriatus* Chapman, 1921 - W Ecuador from Manabí S to Guayas.  
*P. s. sclateri* Taczanowski, 1877 - SW Ecuador (El Oro, Loja) and extreme NW Peru.  
*P. s. porcellae* Bond, 1954 - NW Peru from C Piura S to N Lambayeque.

**Descriptive notes.** 8-9 cm; 9-12.4 g. Male has black forehead to hindneck, feathers of central forehead to about mid-crown narrowly tipped yellow, remainder tipped white; white lores, short white line behind eye; dark ear-coverts streaked white; upperparts dark brownish with darker barring, wing-coverts edged and tipped paler, edges broadest and whitest on tertials; dark grey-brown uppertail, central feather pair with broad white stripe on inner webs, outer 3 pairs with much white subterminally; underparts whitish, chin and throat barred blackish, breast more broadly barred, flanks and belly broadly streaked blackish; underwing whitish.

coverts barred grey; bill short, culmen curved, black with greyer base; iris brown; legs grey. Female has entirely white-spotted top of head. Juvenile duller, forehead and crown with off-white streaks or spots, markings below more diffuse. Race *parvistriatus* is much paler, pale brownish-grey above, secondaries and tertials broadly white-edged, bars below narrow and greyer, sparser streaks much thinner and greyish; *porcellae* has chin and throat bars even broader and blacker than nominate, very broad black bars on breast, very broad black streaks on flanks and belly. **VOICE.** High-pitched "tseeet-tsuit", also single or double "tseeet".

**Habitat.** Dry deciduous forest, and arid areas with cacti and low thorny scrub; also in more humid lower montane forest in SW Ecuador (Loja). From lowlands to 1400 m, locally to 1900 m, rarely to 2100 m; in Ecuador, mostly below 800 m but locally to 1700 m.

**Food and Feeding.** No information on diet; probably similar to that of *P. olivaceus*. Forages at lower levels of habitat.

**Breeding.** Nests from Jun in Peru and from Jul in Ecuador, to Sept. No other information.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Tumbesian Region EBA. Uncommon in Ecuador, where occurs in Machalilla National Park. Uncommon in Peru.

**Bibliography.** Becker & López (1997), Best & Clarke (1991), Bloch *et al.* (1991), Butler (1979), Clements & Shany (2001), Meyer de Schauensee (1982), Olrog (1968), Parker *et al.* (1982), Pople *et al.* (1997), Ridgely & Greenfield (2001), Ridgely *et al.* (1998), Rodner *et al.* (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Taylor (1995), Wheatley (1994), Williams & Tobias (1994).

10. Scaled Piculet

Picumnus squamulatus

**French:** Picumne squamulé    **German:** Schuppenzwergspecht    **Spanish:** Carpinterito Escamoso

**Taxonomy.** *Picumnus squamulatus* Lafresnaye, 1854, Colombia. Race *lovejoyi* possibly not sufficiently distinct to warrant acceptance. Race *obsoletus* almost certainly includes the form previously known as "*P. exilis salvini*", described from "Bogotá" skins with no type locality. Five subspecies currently recognized.

**Subspecies and Distribution.**  
*P. s. rohlfi* J. T. Zimmer & Phelps, Sr., 1944 - N Colombia (Santa Marta Mts S to about Boyacá) and N Venezuela (Zulia E to W Sucre and Monagas).  
*P. s. lovejoyi* Phelps, Jr. & Aveledo, 1987 - extreme NW Venezuela (NW Zulia).  
*P. s. apurensis* Phelps, Jr. & Aveledo, 1987 - NC Venezuela in Apure, Guárico and Anzoátegui (R Zuaata and R Pariaguán).  
*P. s. obsoletus* Allen, 1892 - extreme NE Venezuela (E Sucre).  
*P. s. squamulatus* Lafresnaye, 1854 - NE & C Colombia (Arauca S to Huila and NE Meta).

**Descriptive notes.** 8-9.2 cm; 7-12 g. Male has black forehead to nape, feathers of forecrown narrowly tipped red, those of rest of crown tipped white; whitish lores and thin line behind eye, brown ear-coverts tipped white; hindneck brownish-black, spotted white; upperparts olive-brown and scaly-looking, with paler feather centres and narrow black borders, wing-coverts browner with black fringes; flight-feathers brown, secondaries and tertials with broad yellowish edges; uppertail brownish-black, central feather pair with broad white stripe on inner webs, outer 2 pairs with white subterminal stripe; malar, chin and

throat white with narrow grey-brown feather tips; rest of underparts whitish with prominent scaly markings, dark brown to black feather margins becoming paler and narrower on belly and undertail-coverts; underwing brownish with white coverts; bill short, culmen curved, grey, paler on lower mandible, blackish tip; iris brown; legs grey to olive-grey. Female has forecrown spots white. Juvenile darker above, often with darker feather centres, more diffusely and irregularly patterned below. Race *rohlfi* has forecrown spots of male sometimes yellow or orange, hindcrown paler, upperparts brighter, underparts with narrower scaly markings, belly tinged brownish-yellow; *lovejoyi* is similar, but male forecrown spots always yellow instead of red, greyer upperparts; *obsoletus* is tinged yellow-green above, yellowish-white below with finer paler scallop markings and small dark wedge-shaped streaks in feather centres; *apurensis* is whiter-looking below, scaly markings narrow and indistinct. **VOICE.** Rather high-pitched squeaky "chi-chi-ch'e'c'chi", becoming trill-like at end.

**Habitat.** Inhabits gallery forest, forest edge, second growth, and deciduous woodland; also found in open terrain and in farmland with scattered trees, xerophytic areas, and pastures. Occurs from lowlands up to 1900 m.

**Food and Feeding.** Small insects. Forages singly or in pairs, in dense scrub, tangled undergrowth and small trees. Investigates thin branches and twigs.

**Breeding.** Birds in breeding condition in Jan and Oct in Colombia; nesting in Apr-Jun and Sept in Venezuela. Displays include wing-spreading and "synchronized" movements. No other information.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. No data on population sizes. Possibly not uncommon, and may perhaps be overlooked owing to inconspicuous behaviour. Occurs in Henri Pittier and Cueva de los Guácharos National Parks (Venezuela).

**Bibliography.** Friedmann & Smith (1950), Hilty & Brown (1986), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Phelps & Aveledo (1987), Rodner *et al.* (2000), Salaman *et al.* (1999), Stotz *et al.* (1996), Vereá & Solórzano (1998), Vereá *et al.* (1999), Wetmore (1939), Wheatley (1994), Zimmer & Phelps (1944).

## 11. White-bellied Piculet

### *Picumnus spilogaster*

**French:** Picumne à ventre blanc

**Spanish:** Carpinterito Ventri blanco

**German:** Weißbauch-Zwergspecht

**Other common names:** Sundevall's Piculet; Para Piculet (*pallidus*)

**Taxonomy.** *Picumnus spilogaster*, Sundevall, 1866, the Guianas.

Sometimes considered to include *P. nigrapunctatus*, but the two are vocally different. Race *pallidus* sometimes considered a separate species, or treated as a race of *P. minutissimus*, but appears very close morphologically to other forms of present species. Form previously listed as "*P. leucogaster*", described from R Cauamé (Roraima), is a synonym of nominate *spilogaster*, further sampling having shown complete gradation towards typical *spilogaster*; possibly represents a link between nominate and *orinocensis*, showing some intermediate features. Three subspecies currently recognized.

#### Subspecies and Distribution.

*P. s. orinocensis* J. T. Zimmer & Phelps, Sr., 1950 - C Venezuela, from SE Apure E along R Meta and R Orinoco to Delta Amacuro.

*P. s. spilogaster* Sundevall, 1866 - N parts of the Guianas, and N Brazil (Roraima).

*P. s. pallidus* Snethlage, 1924 - NE Brazil in E Pará (Belém area).

**Descriptive notes.** c. 9 cm; 13-14 g. Male has top of head black, crown with broad red feather tips forming fairly solid patch, hindcrown to nape spotted white; buffish lores, dark brown ear-coverts vermiculated white; neck sides white, finely barred black; dull olive-brown hindneck and upperparts diffusely barred pale greyish, wing-coverts olive-brown with narrow pale edges; brown flight-feathers edged light buffish, edges broadest and brightest on secondaries and tertials; uppertail dark brown, central feather pair with broad white stripe on inner webs, outer 2 pairs with white stripe on outer webs

except tips; malar, chin and throat whitish, barred blackish; upper breast washed pale yellowish-buff with fairly broad, sometimes broken, black bars, lower breast to belly cream-white with sparse broad black spots, flanks occasionally barred; underwing grey-brown, coverts white; bill short, culmen slightly curved, slate-grey with black tip; iris brown; legs greenish-grey. Differs from *P. minutissimus* in smaller size, less marked upperparts, barred and spotted (not scaled) underparts, dark eyes. Female lacks red on head. Juvenile has crown sooty-brown, buffish spots restricted to hindneck, more buffish underparts, is generally more barred both above and below. Race *orinocensis* is slightly smaller, usually unmarked below or occasionally with trace of vermiculation on flanks, slightly more white in tail; race *pallidus* resembles nominate, but slightly smaller, tail proportionately shorter. Voice. Song a high-pitched thin trill c. 3 seconds long, c. 25-35 notes on slightly descending scale.

**Habitat.** Inhabits rainforest, gallery forest and deciduous forest, clearings, forest edge, and also mangroves; also found in open woodland and thickets. Occurs from lowlands up to 100 m.

**Food and Feeding.** Diet unrecorded. Observed singly and in pairs, but no documented information on foraging behaviour.

**Breeding.** Probably Sept-Nov. No information on nest or breeding biology.

**Movements.** Apparently resident.

**Status and Conservation.** Not globally threatened. Poorly known, and no data available on numbers. Locally not uncommon in llanos of Venezuela.

**Bibliography.** Hilty (1999), Meyer de Schauensee & Phelps (1978), Reynaud (1998), Rodner *et al.* (2000), Ruschi (1979), Sick (1993), Stotz *et al.* (1996), Tostain *et al.* (1992), Wheatley (1994).

## 12. Guianan Piculet

### *Picumnus minutissimus*

**French:** Picumne de Cayenne

**German:** Däumlingsspecht

**Spanish:** Carpinterito de Guayana

**Other common names:** Arrowhead Piculet

**Taxonomy.** *Picus minutissimus* Pallas, 1782, Cayenne.

Sometimes considered to include race *pallidus* of *P. spilogaster*. Monotypic.

**Distribution.** Coastal lowlands from Guyana E to French Guiana.

**Descriptive notes.** 9-10 cm; 11-16 g. Male has top of head black, crown with broad red feather tips forming solid patch, rest spotted white; buff-white lores, short white line behind eye, dark brown cheeks and ear-coverts with white feather fringes; rear neck side white, barred or spotted black; upperparts olive-brown, feathers with blackish wedge-shaped centre, very thin black bar at tip, and pale subterminal spot or diffuse bar; plainer rump obscurely dark-barred, uppertail-coverts sometimes barred pale and dark; wing-coverts olive-brown with paler edgings; flight-feathers brown, secondaries and tertials broadly edged buffish-white on outer

webs; uppertail brownish-black, central feather pair with broad white stripe along inner webs, outer 2 pairs with angled white stripe on outer webs; malar, chin and throat white, narrowly barred black; rest of underparts white, tinged brownish-buff on belly and lower flanks, all with brownish-black feather fringes creating distinctive scaly pattern; underwing grey-brown, coverts mottled brown and white; bill short, stout, culmen curved, dark grey with pale base of lower mandible; iris yellow to deep red or red-brown, orbital skin greyish; legs green-grey. Distinguished from *P. spilogaster* and *P. cirratus* by upperpart markings, brownish belly, entirely scaly underparts. Female lacks red on head, has slightly shorter bill, slightly longer wing and tail. Juvenile has unspotted dark brown

crown, browner upperparts barred blackish, duller underparts less clearly patterned. Voice. Series of c. 14 thin notes, "it-it-it-it...", or "kee kee kee", reminiscent of Old World *Dendrocopos minor*; loud twitter in aggressive attacks.

**Habitat.** Wide variety of habitats, including secondary forest, plantations, mangroves, riverine and lakeside vegetation, up to montane forest.

**Food and Feeding.** Ants and small beetles (Bostrichidae) recorded as forming part of diet. Forages in shrubs and trees in manner of a tit (Paridae), hanging from small branches and twigs; hammers on branches.

**Breeding.** Season Mar-Dec. Nest-hole excavated mostly by male, high up (e.g. 8 m) in tree; during breeding, other birds, even bigger ones, are attacked in vicinity of nest. Clutch 2-3 eggs; incubation by both sexes, period 12-14 days; both adults also feed the young and remove faeces; fledging c. 28 days; parents and young stay together for at least a further 2 months, and adults often accompanied in roost-hole by a third individual (presumably from previous brood) until next breeding attempt.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. No details available on population sizes. Species is considered common in Surinam, and probably also common in rest of range.

**Bibliography.** Haverschmidt (1951), Haverschmidt & Mees (1994), Meyer de Schauensee (1982), Motta-Júnior (1990), Olrog (1968), Rodner *et al.* (2000), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Wheatley (1994), Willis & Oniki (1990).

## 13. Spotted Piculet

### *Picumnus pygmaeus*

**French:** Picumne ocellé

**German:** Fleckenzwergspecht

**Spanish:** Carpinterito Ocellado

**Taxonomy.** *Picus pygmaeus* M. H. K. Lichtenstein, 1823, Brazil = Bahia.

Monotypic.

**Distribution.** E Brazil, from C Maranhão and Piauí E to Pernambuco, and S to NE Goiás and extreme N Minas Gerais.

**Descriptive notes.** 10 cm. Distinctive with dark plumage spotted with white. Male has top of head black, forecrown with broad red feather tips forming solid patch, rest of crown and nape spotted white; buff-white lores, often white crescent above eye, dark brown cheeks and ear-coverts variably spotted white; moustachial region and neck sides broadly barred white; dark brown upperparts with prominent black-based whitish tips on mantle, scapulars and back, rump paler; wing-coverts edged paler, broadly tipped white; flight-feathers darker brown, secondaries and tertials broadly edged and tipped light buff or cinnamon-buff; uppertail blackish, central feather pair with broad white stripe along inner webs, outer 2 pairs with white subterminal area; chin and throat variable, black with large white spots or mainly white with black scale-like markings; rest of underparts darkish brown to medium or light brown, usually tinged rufous, often paler on belly, with large white spots each with contrasting black mark at base and tip, spots usually larger on flanks; underwing pale brownish, coverts whitish; undertail as uppertail, but paler; bill short, culmen very slightly curved, black with blue-grey base; iris deep brown; legs grey. Female lacks red on head. Juvenile is duller, more diffusely patterned, markings below tending towards bars. Voice. Distinctive, very high-pitched, squeaky "tsirrrrr, tsi, tsi, tsi".

**Habitat.** Dry and open woodland and dense shrubs (*caatinga*), at up to 750 m.

**Food and Feeding.** No information available.

**Breeding.** No definite information. Season possibly Nov-Feb, possibly also Jul.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. A poorly known species. No information on numbers. Probably uncommon, or overlooked.

**Bibliography.** Meyer de Schauensee (1982), Olrog (1968), Pinto & Camargo (1961), Ruschi (1979), Sargeant & Wall (1996), Sick (1993), Stotz *et al.* (1996), Tobias *et al.* (1993), Wheatley (1994), Willis (1992).

## 14. Speckle-chested Piculet

### *Picumnus steindachneri*

**French:** Picumne perlé

**German:** Perlenbrust-Zwergspecht

**Spanish:** Carpinterito Perlado

**Taxonomy.** *Picumnus steindachneri* Taczanowski, 1882, Chirimoto, Peru.

Monotypic.

**Distribution.** Andes of NW Peru in SE Amazonas and NW San Martín (region of R Huallaga and its tributaries).

**Descriptive notes.** 10 cm; 9-11 g. Very distinctive piculet. Male has top of head black, feathers of forecrown broadly tipped red, rest of crown and hindneck spotted white; creamy lores and nasal tufts; sides of head and neck white with black bars; grey-brown upperparts with obscure paler greyish feather fringes and darker submarginal borders, producing slightly scalloped pattern; brown wings and wing-coverts edged and tipped pale grey to off-white, edges broadest on secondaries and tertials; uppertail blackish, central feather pair with white stripe along inner webs, outer 2 pairs with white subterminal area; white chin and throat

with narrow black fringes; black breast with large drop-shaped white spots, white belly to undertail-

coverts broadly barred black; underwing pale brown, coverts white; bill short, almost straight, black, with blue-grey base and most of lower mandible; iris brown; legs grey. Female lacks red on crown. Juvenile not described; presumably duller and less clearly patterned than adults. Voice. High-pitched trill, lasting several seconds; fledged young beg noisily.

**Habitat.** Inhabits humid tropical and subtropical montane forest with many epiphytes and tall second growth; observed also in newer second growth (2.5 m tall) in cultivated terrain, and in bamboo stands mixed with other plants. Mainly found between 1150 m and 1800 m, but regularly up to c. 2300 m, and locally perhaps up to 2500 m; occasionally occurs at lower altitudes, down to c. 900 m.

**Food and Feeding.** No data available on diet. Forages singly, in pairs or in small family groups; also joins mixed-species flocks, moving with them through canopy and second growth. Forages low down in dense shrubbery, and to 10–12 m up at the end of thin twigs and on vines; hammers loudly.

**Breeding.** No information available.

**Movements.** Resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Ecuador-Peru East Andes EBA. Tiny range covers c. 7000 km<sup>2</sup>, within which it has been recorded at no more than 5 localities, and is probably extinct at one of those (Mendoza, in SE Amazonas). No accurate data on numbers; population estimated at fewer than 10,000 individuals, and declining. Occurs in Alto Mayo Protected Forest, where locally quite common, e.g. at Abra Patricia. Primary threat is habitat loss and degradation; logging has occurred in area since at least 1930; deforestation for coca plantations a threat in 1980's, but commercial production seems now to have ceased. Continuing increase in human population and incursion has led to heavy disturbance of forest, including both clear-cutting and selective logging, and in SE of species' range forest is now confined to highest slopes; large areas have been converted to agriculture, especially coffee plantations, and pastures; even in Alto Mayo Protected Forest, designated in 1986 to protect R Alto Mayo watershed for agricultural sustainability, forest clearance has continued unchecked. Media interviews and discussions with local leaders have been utilized to inform people of urgent need to protect region's forests. Co-operation with local agricultural bodies recommended as a further tool to promote conservation. In addition, surveys are needed in order to establish this species' true population size and ecological requirements, as well as its precise distribution.

**Bibliography.** Begazo *et al.* (2001), Clements & Shany (2001), Collar *et al.* (1994), Hornbuckle (1999), Meyer de Schauensee (1982), Olog (1968), Parker *et al.* (1982), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wheatley (1994).

## 15. Varzea Piculet

### *Picumnus varzeae*

**French:** Picumne des varzéas **German:** Varzeazwergspecht **Spanish:** Carpinterito de las Várzeas

**Taxonomy.** *Picumnus varzeae* Sneathlage, 1912, Fazenda Paraíso, near Faro, Pará, Brazil.

Apparently hybridizes occasionally with *P. cirratus*. Monotypic.

**Distribution.** Amazonian Brazil, between lower R Madeira in E Amazonas and Obidos in extreme NW Pará, including the river islands.

**Descriptive notes.** 8–9 cm. Male has black forehead and crown, all but lowermost forehead with broad red feather tips forming solid patch; hindcrown and nape black, spotted white; white lores speckled black; sides of head and neck dark brown, feathers tipped black and obscurely vermiculated or spotted whitish; hindneck and upperparts dark olive-brown to greenish-brown, sometimes with a few faint black bars; dark brown underwing and wing-coverts narrowly edged and tipped paler, edges broader and brighter on secondaries and tertiaries; uppertail dark brown, central feather pair with white stripe along inner webs, outer pair with white stripe along throat black-brown, finely spotted or barred white; rest of underparts variable in colour and markings, generally brown or greenish-brown with rows of broadly white-tipped black feathers; underwing pale brownish, coverts barred white; bill short, culmen slightly curved, black with blue-grey base, sometimes dull yellowish base of lower mandible; iris brown; legs grey. Female has entire top of head black with white spots. Juvenile more barred below. Voice. Not documented.

**Habitat.** Lowland várzea with dense undergrowth.

**Food and Feeding.** No information.

**Breeding.** Season possibly Jun–Dec. No other information.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Amazon Flooded Forests EBA. Little-known species. No information available on numbers or on relative densities. Small range may suggest a rather small total population, but no known threats currently exist. Data required on this species' ecology and breeding biology.

**Bibliography.** Meyer de Schauensee (1982), Olog (1968), Rusehi (1979), Sick (1993), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wheatley (1994).

## 16. White-barred Piculet

### *Picumnus cirratus*

**French:** Picumne frangé **German:** Zebrazwergspecht **Spanish:** Carpinterito Variable  
**Other common names:** Pilcomayo Piculet (SW races)

**Taxonomy.** *Picumnus cirratus* Temminck, 1825, Brazil and Paraguay.

Forms a superspecies with *P. dorbignyanus* and *P. temminckii*, and sometimes treated as conspecific with one or the other, or both; hybridizes frequently with latter in SE Brazil (São Paulo and Paraná), also occasionally with former in Bolivia. Also interbreeds to limited extent with *P. albosquamatus* and apparently with *P. varzeae*. SW races *thamophiloides*, *tucumanus* and *pilcomayensis* intergrade in N Argentina, and sometimes considered together to form a separate species, but last of those also intergrades with nominate race in E Paraguay. Also, N races *confusus* and *macconnelli* possibly form a distinct species. Further study needed to clarify relationships of this entire complex of taxa. Six subspecies currently recognized.

#### Subspecies and Distribution.

*P. c. confusus* Kinnear, 1927 - SW Guyana, extreme N Brazil (E Roraima) and French Guiana.  
*P. c. macconnelli* Sharpe, 1901 - E Amazon region of NE Brazil (W to lower R Tapajós).  
*P. c. thamophiloides* Bond & Meyer de Schauensee, 1942 - SE Bolivia (Chuquisaca) S along Andes to NW Argentina (N Salta).  
*P. c. tucumanus* Hartert, 1909 - N Argentina (W Salta S to La Rioja).  
*P. c. pilcomayensis* Hargitt, 1891 - SE Bolivia (S Santa Cruz, E Tarija) and Paraguay S to N Argentina (S to Santiago del Estero, N Buenos Aires and N Corrientes).  
*P. c. cirratus* Temminck, 1825 - SE Brazil (from N Minas Gerais and Espírito Santo S to Paraná), S Mato Grosso and E Paraguay.

**Descriptive notes.** 10 cm; 6–8–12 g. Male has black forehead to nape, crown feathers with broad red tips often forming fairly solid patch, remainder spotted white; white to buffish nasal tufts; dark buff-brown cheeks and ear-coverts faintly barred blackish, bordered above by white stripe behind eye; buff moustachial area and neck sides barred blackish; dull brownish upperparts sometimes faintly barred, brown wing-coverts narrowly edged buffish; flight-feathers dark brown, secondaries and tertiaries edged buffish-white; uppertail dark brown, central feather pair with white stripe along inner webs, outer 2 or 3 pairs with diagonal white

subterminal area; chin and throat white to pale buff, barred blackish; rest of underparts white, belly and flanks tinged buff, all fully barred black; underwing pale brown, coverts paler; bill fairly short, culmen slightly curved, black with distinctly paler base of lower mandible; iris dark chestnut-brown, orbital skin blue-grey; legs grey. Differs from *P. dorbignyanus* in browner upperparts, barred rather than scaly underparts; from *P. temminckii* in lack of cinnamon-buff tones above and below. Female lacks red tips on crown feathers. Juvenile duller and darker, lacks white crown spots, tends to show more obvious barring above and heavier barring below. Race *confusus* has darker ear-coverts lacking white upper border, brown upperparts with pale mantle bars, very narrow pale wing edgings, well-barred throat; *macconnelli* is similar above but unbarred, has deep brown ear-coverts sometimes white-spotted, heavier broader bars on moustachial area, throat and breast; *thamophiloides* is greyish above, less marked below, throat and upper breast with few dark bars, flanks with variable arrowheads or Y-marks, belly almost plain; *tucumanus* has grey-brown upperparts more distinctly barred, buffier throat and breast more obscurely barred, more widely spaced black bars below, male has red restricted to forecrown, often reduced white crown spots; *pilcomayensis* is also greyish above, has narrower black and white barring below, barring sometimes broken, male has reduced red on crown. Voice. High descending or long and wavering "tsirrr" used apparently for long-range communication; also "tsirit, tsick"; drums a loud staccato on small dead stub.

**Habitat.** Frequents tall bushes and gallery forest of savannas, as well as open woodland and edges, transitional forest and scrub. Present from lowlands up into mountains, occurring at up to 2100 m.

**Food and Feeding.** Small insects, including ants; also insect larvae and eggs, especially of wood-boring beetles; possibly also sap, obtained by wounding the tip of a twig. Generally hunts singly, sometimes with mixed-species flocks; rather tame. Forages at low and middle heights, mainly in undergrowth. Seen mostly at tips of branches and on twigs, often clinging to the underside; also gathers food from vines, small trees and bamboo. Main feeding technique is vigorous and audible hammering, whereby it excavates small holes in the substrate. Actions typical of piculets; sometimes moves downwards like a nuthatch (*Sitta*). Flies considerable distances between foraging sites.

**Breeding.** Jul–Dec in N, Sept–Mar in S. Nest-hole excavated by both sexes, at varying height but often low down, in slender stub or narrow stem, but also recorded in broader trunk 22.5 cm wide; circular or oval entrance with dimensions 2.3–7 cm, long hole 10–20 cm deep, internal diameter 5–6.3 cm. Launches pecking attacks on opponents, but without hitting. Clutch 2–4 eggs; no information on incubation and fledging periods.

**Movements.** Probably resident.

**Status and Conservation.** Not globally threatened. Fairly common locally; locally common in Argentina; probably common in some places, but no detailed data on numbers or densities. Occurs in Itatiaia National Park, Serra do Cipó National Park, Rio Doce State Park, Nova Lombardia Biological Reserve and Sooretama Biological Reserve, in Brazil; in El Rey National Park and Calilegua National Park in Argentina; and in Ybicui National Park in Paraguay. No known threats to population as a whole; locally threatened by continuing deterioration of remnant forest habitat, e.g. in N Buenos Aires (Argentina).

**Bibliography.** Alves *et al.* (1997), dos Anjos & Schuchmann (1997), Belton (1984), Bodrati *et al.* (2001), Brooks *et al.* (1993), Buzzetti (2000), Canevari *et al.* (1991), Capper *et al.* (2000), Contreras (1983), Contreras *et al.* (1990), Dubs (1992), Ferreira de Vasconcelos & Melo-Júnior (2001), Figueiredo & Lo (2000), Figueiredo *et al.* (2000), Fjeldså & Mayer (1996), Friedmann (1927), Giraudo *et al.* (1993), Goerck (1999), Hayes (1995), López (1997), Maldonado-Coelho & Marini (2000), Melo-Júnior (2001a), Parker & Goerck (1997), de la Peña (1994), Remsen & Traylor (1989), do Rosário (1996), Schmitt *et al.* (1997), Scott & Brooke (1985), Short (1975), Sick (1993), da Silva *et al.* (1997), Silveira (1998), Snyder (1966), Stotz *et al.* (1996), Tobias *et al.* (1993), Tostain *et al.* (1992), Wetmore (1926).

## 17. Ocellated Piculet

### *Picumnus dorbignyanus*

**French:** Picumne d'Orbigny **German:** Orbignyzwergspecht **Spanish:** Carpinterito Boliviano

**Taxonomy.** *Picumnus d'Orbignyanus* Lafresnaye, 1845; no locality = Bolivia.

Forms a superspecies with *P. cirratus* and *P. temminckii*, and sometimes treated as conspecific with former, or with both. Interbreeds with former and with *P. albosquamatus*. Apparently as the result of a perpetuated error, species name has almost universally been misspelt "dorbignianus", but in original description scientific name incorporated d'Orbigny's name correctly spelt, so rectification is required. Two subspecies recognized.

#### Subspecies and Distribution.

*P. d. jelskii* Taczanowski, 1882 - Andes of E Peru.  
*P. d. dorbignyanus* Lafresnaye, 1845 - C Bolivia (La Paz, Cochabamba, W Santa Cruz) and extreme NW Argentina (Jujuy, Salta).

**Descriptive notes.** 10 cm. Relatively pale-looking. Male has top of head black, crown feathers tipped red, hindcrown and nape spotted white; buffish-white lores and nasal tufts; buff-brown cheeks and ear-coverts streaked whitish, bordered above by short white stripe behind eye; buffy-white neck sides with darker streaking; hindneck pale grey-brown; upperparts grey-brown, usually some

feathers with pale tip and blackish subterminal bar, wing-coverts narrowly edged paler; dark brown flight-feathers prominently edged and tipped buffish-white; uppertail blackish, central feather pair with broad white stripe on inner webs, outer 2 pairs with diagonal white subterminal area; malar, chin and throat whitish, faintly buff-tinged, with dark feather edges sometimes giving throat scaly appearance; rest of underparts white, belly buffish, breast and flank feathers with black centres or shaft streaks and thin dark edges, belly unmarked or with some faint narrow bars; underwing pale grey-brown, coverts whitish; bill fairly short, culmen

barely curved, black with grey base; iris brown, orbital skin greyish; legs greyish. Female lacks red feather tips on crown. Juvenile duller and slightly darker than adult, diffusely barred above and below. Race *jelskii* has shorter tail than nominate, markings below generally more restricted to broad black shaft streaks on breast, finer streaking on flanks, fewer dark spots on belly. Voice. High-pitched trill, similar to that of *P. cirratus*.

**Habitat.** Humid tropical and subtropical montane and submontane forest with many epiphytes; also tall bushes in transitional forest in Argentina. Between 900 m and 2500 m; 1100-2200 m in Peru.

**Food and Feeding.** No details available on diet. Usually observed singly or in pairs; often accompanies mixed-species flocks. Commonly hangs upside-down on twigs and branches like a nuthatch (*Sitta*).

**Breeding.** No definite information; probably breeds before Dec.

**Movements.** Presumably resident; possibly some vertical movements.

**Status and Conservation.** Not globally threatened. Uncommon and local in Peru, but quite common in some places (e.g. between Aguas Calientes and Mandor Valley); probably uncommon to rare in rest of range. Occurs in Machu Picchu Historical Sanctuary in Peru.

**Bibliography.** Blendinger (1998), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Clements & Shany (2001), Fjeldså & Mayer (1996), Mazar Barnett & Pearman (2001), Narosky & Yzurieta (1993), Olog (1958), Parker *et al.* (1982), Schmitt *et al.* (1997), Short (1975), Stotz *et al.* (1996), Walker (2001), Wheatley (1994), Zimmer (1930).

## 18. Ochre-collared Piculet

*Picumnus temminckii*

**French:** Picumne de Temminck

**Spanish:** Carpinterito Cuellicanela

**German:** Temminckzwergspecht

**Taxonomy.** *Picumnus Temminckii* Lafresnaye, 1845, Paraguay.

Forms a superspecies with *P. cirratus* and *P. dorbignyanus*, and sometimes treated as conspecific with former, or alternatively with both. Hybridizes frequently with nominate race of former, producing many intermediate individuals; also occasionally interbreeds with race *guttifer* of *P. albosquamatus*. Monotypic.

**Distribution.** E Paraguay, NE Argentina (Misiones) and SE Brazil (São Paulo S to Rio Grande do Sul).

**Descriptive notes.** 9-10 cm; 10-12.5 g. Male has top of head black, feathers of forecrown tipped red, hindcrown and nape finely spotted white; buff-white lower forehead, lores and nasal tufts; rich buff-brown cheeks and ear-coverts bordered above by bright buff-white or white line behind eye; broad cinnamon-buff hindneck-collar, often brighter at junction with nape; brown upperparts plain or very faintly barred paler, brown wing-coverts edged buff; flight-feathers dark brown, narrowly edged buff; uppertail blackish, central feather pair with white stripe on inner webs, outer 2 pairs with diagonal white subterminal area; malar,

chin and throat pale buffish-white, feathers narrowly tipped blackish; rest of underparts whitish, becoming strongly buff on flanks and lower belly, all with bold but rather narrow black bars; underwing light brown, coverts whitish; bill short, culmen slightly curved, black with greyish base; iris brown, orbital skin greyish; legs greyish. Female lacks red on crown. Juvenile darker and duller than adult, heavier but more diffuse barring below. Voice. High-pitched whistle, "tsirrrr, si-si-si..."; drums loudly in short bursts of strokes, similar to drumming of *P. nebulosus* but slower.

**Habitat.** Inhabits tall scrub and *tacuarales* of humid forest, and forest edge.

**Food and Feeding.** Very little known. Diet includes ants (*Myrmelachista*) and insect larvae. Forages at low levels, usually on slender stalks, also on thin, hollow branches.

**Breeding.** No definite data; presumably nests in Oct-Mar.

**Movements.** Apparently resident.

**Status and Conservation.** Not globally threatened. No data available on numbers; fairly common, at least locally, e.g. at Urugua-i Provincial Park in Misiones (N Argentina). Occurs in neighbouring Iguazú and Iguazú National Parks (Brazil/Argentina).

**Bibliography.** Aleixo & Galetti (1997), dos Anjos (2001), dos Anjos & Schuchmann (1997), dos Anjos *et al.* (1997), Belton (1984), Bencke & Kindel (1999), Canevari *et al.* (1991), Guix *et al.* (1992), Hayes (1995), Hinkelmann & Fiebig (2001), Krügel & dos Anjos (2000), Lencioni-Neto (1995), Lowen *et al.* (1995), Madroño, Clay, Robbins *et al.* (1997), Mazar Barnett & Pearman (2001), Mendonça-Lima *et al.* (2001), Narosky & Yzurieta (1993), Parker & Goerck (1997), de la Peña (1994), Ruschi (1979), Saibene *et al.* (1996), Sick (1993), Soares & dos Anjos (1999), Stotz *et al.* (1996), Tobias *et al.* (1993).

## 19. White-wedged Piculet

*Picumnus albosquamatus*

**French:** Picumne noir et blanc

**Spanish:** Carpinterito Albiescamoso

**German:** Weißschuppen-Zwergspecht

**Other common names:** Guttate Piculet (*guttifer*); Blackish Piculet ("*P. asterias*")

**Taxonomy.** *Picumnus albosquamatus* d'Orbigny, 1840, Río Tamanipaya, Yungas, Bolivia.

Hybridizes with *P. dorbignyanus*, also to limited extent with *P. cirratus*, and occasionally with *P. temminckii*. Race *guttifer* formerly considered a separate species, but appears to intergrade with nominate in W Mato Grosso; these mixed populations probably account for the form previously listed as race *P. a. corumbanus*. Forms described as species "*P. asterias*", known only from single type specimen, and "*P. sagittatus*" are indistinguishable from variable race *guttifer*, and are thus synonymized with it. Two subspecies currently recognized.

**Subspecies and Distribution.**

*P. a. guttifer* Sundevall, 1866 - E & C Brazil, from S Pará and S Maranhão S to S & E Mato Grosso and W São Paulo.

*P. a. albosquamatus* d'Orbigny, 1840 - NC & E Bolivia and SW Brazil (in SW Mato Grosso), and adjacent N Paraguay.

**Descriptive notes.** 10-11 cm; 9-11 g. Male has top of head black, forecrown feathers broadly tipped red, hindcrown and crown sides to nape finely spotted white; buffish-white nasal tufts and lores bordered by black line across lower forehead; whitish side of head to hindneck strongly tinged brown, with black feather margins, white line behind eye; upperparts warm brown to greyish-brown, often some feathers with variable pale tips; brown wing-coverts broadly pale-edged; flight-feathers dark brown, secondaries and tertials with broad buffish-white edges on outer webs; uppertail dark brown, central

feather pair with broad white stripe on inner webs, outer 2 pairs with broad diagonal white subterminal area; white malar, chin and throat with black borders to feathers, appearing scaly; rest of underparts whitish, variably washed pale buff, breast with narrow black feather borders giving scalloped effect, flanks almost unmarked or with subterminal black wedges, belly plain or slightly streaked; underwing pale brown, coverts whitish; longish bill pointed, culmen barely curved, blackish with paler base of lower mandible; iris brown, orbital skin greyish; legs grey to green-grey. Female lacks red on head. Juvenile duller, less contrastingly patterned than adults, more barred appearance. Race *guttifer* is bigger than nominate, with plumage variable; typically darker, has more contrasting dark brown ear-coverts, distinct pale spots on wing-covert tips, often more black-centred pale-edged feathers above, black shaft streaks and broader black feather borders on throat and breast (can appear largely black), warm buff lower underparts with broad black wedges, male with more red on crown. Voice. Descending "si-si-si...".

**Habitat.** Occupies denser parts of open, moderately dry savanna woodland (*cerrado*), and also gallery forest. Present in lowlands and foothills, locally occurring up to 2100 m.

**Food and Feeding.** No information.

**Breeding.** Juveniles collected from end May to Dec in Bolivia, and Jun-Dec in Mato Grosso. One nest-hole c. 3 cm wide being excavated 1.5 m up in fence post in Sept, Pantanal. No further information.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. No precise data on population sizes, but locally not uncommon in N Pantanal, around Poconé. Occurs in Brasília, Pantanal do Mato Grosso and Chapada dos Guimarães National Parks (Brazil).

**Bibliography.** Aleixo (1997), dos Anjos (2001), Bracc *et al.* (1997), Cândido (2000), Contreras *et al.* (1993), Dubs (1992), Hayes (1995), Lencioni-Neto (1995), Marini *et al.* (1997), Meyer de Schauensee (1982), Olog (1968), Oniki & Willis (1999), Perry *et al.* (1997), Piratelli *et al.* (2000), Ruschi (1979), Sick (1993), da Silva (1996), Stager (1961a), Stotz *et al.* (1996), Tubelis & Tomás (1999), Willis & Oniki (1991).

## 20. Rusty-necked Piculet

*Picumnus fuscus*

**French:** Picumne à nuque rousse

**Spanish:** Carpinterito Cuellirrufo

**German:** Rostnacken-Zwergspecht

**Other common names:** Natterer's Piculet

**Taxonomy.** *Picumnus fuscus* Pelzel, 1870, Rio Guaporé, Mato Grosso, Brazil.

Although generally considered to be related to the "*P. cirratus* complex" or to *P. rufiventris*, may possibly be closer to *P. aurifrons* or *P. exilis*. Monotypic.

**Distribution.** R Guaporé drainage in NE Bolivia (Beni) and WC Brazil (extreme W Mato Grosso).

**Descriptive notes.** 10 cm. Distinctive piculet with unique head pattern. Male has top of head blackish, feathers of hindcrown broadly tipped reddish-orange; buffish lores, sides of lower forehead and nasal tufts; buffish-brown cheeks and ear-coverts tinged rufous, broken pale stripe behind eye; hindneck and neck side rusty-buff to buff-brown; upperparts brown to brownish-green, scapulars often tinged rufous; upwinging dark brown, wing-coverts with paler borders, secondaries and tertials edged yellowish-buff; uppertail dark brown, central feather pair with broad white stripe on inner webs, outer 2 pairs with narrower diagonal white bar;

buff malar region usually faintly dark-barred, buff-brown chin and throat occasionally with trace of fine barring; rest of underparts pale buffish, breast sides and flanks tinged cinnamon or light rusty, either unmarked or with faint vestigial barring on flanks and, occasionally, breast and belly; underwing pale brown, coverts rufous-buff; bill short, culmen slightly curved, black with paler base; iris brown, orbital skin greyish; legs greyish-brown. Female lacks reddish feather tips on head. Juvenile apparently undescribed. Voice. Not documented.

**Habitat.** Lowland riverine forest (*várzea*).

**Food and Feeding.** Not documented.

**Breeding.** No information.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. No details on numbers; possibly not uncommon, but is restricted to a particular habitat type (*várzea*) within a very small range. Occurs in Noel Kempff Mercado National Park in Bolivia. Appears to be reasonably secure, but increasing human settlement along the currently largely uninhabited banks of the R Guaporé could become a threat. Little is known of the species' ecology and breeding biology; research required.

**Bibliography.** Dubs (1992), Mazar Barnett & Kirwan (2000), Parker & Rocha (1991), Remsen & Traylor (1989), Ruschi (1979), Sick (1993), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wheatley (1994).

## 21. Rufous-breasted Piculet

### *Picumnus rufiventris*

**French:** Picumne à ventre roux

**Spanish:** Carpinterito Ventrirrufo

**German:** Rotbauch-Zwergspecht

**Taxonomy.** *Asthenurus rufiventris* Bonaparte, 1838, western Brazil near border with Peru.

Three subspecies recognized.

**Subspecies and Distribution.**

*P. r. rufiventris* (Bonaparte, 1838) - E slope of Andes from C & S Colombia (N Meta S to SE Nariño, Putumayo and Amazonas) to E Ecuador, NE Peru and W Amazonian Brazil.

*P. r. grandis* Carriker, 1930 - CE Peru (W to Huánuco and Junín) and neighbouring SW Amazonian Brazil.

*P. r. brunneifrons* Stager, 1968 - NW & C Bolivia (Pando, Beni, Cochabamba).

**Descriptive notes.** 9-11 cm; 12-16 g, 21 ♀ (*grandis*). Male has black forehead to nape, crown feathers tipped red, rest spotted white to buff, most prominently on nape; white lores and nasal tufts variably tipped black; rest of head and hindneck rufous to cinnamon-rufous, ear-coverts often darker; dark green upperparts usually tinged rufous, especially on rump; dark brown upperwing, wing-coverts edged and tipped greenish, secondaries and tertials edged cinnamon on inner webs and rusty on outer webs and tips; uppertail dark brown, central feather pair with pale cinnamon stripe on inner webs, outer 2 pairs with cinnamon stripe on outer webs; entire underparts plain rufous; underwing brown, coverts rufous; bill comparatively long, straight, blackish with slightly paler base of lower mandible; iris brown, orbital skin greyish-blue; legs grey. Differs from similar *P. cinnamomeus* in dark forehead, red (not yellow) on crown, darker orbital ring, greener upperparts. Female has entire top of head spotted white. Juvenile is grey-tinged above, less rufous on hindneck,

has breast and flanks grey, belly sometimes grey-barred. Race *grandis* is bigger than nominate, has upperparts tinged yellowish, underparts paler, black cap ending higher on nape, male with more red on crown; *brunneifrons* is intermediate in size, has plumage similar to previous but darker, upperparts with stronger rufous-chestnut suffusion. **VOICE.** Quiet; occasional high thin "tseeeyt-tseeeyt-tsit", notes dropping in pitch.

**Habitat.** Humid forest in thick understorey of forest edge, also in second growth, including overgrown clearings, and vegetation along watercourses; also locally in tangled clearings

and edges inside *terra firme* and *várzea* forest; typically found in stands of bamboo. Mostly at lower elevations up to 400 m; locally higher, to 900 m, in Peru; in Ecuador mostly below 1100 m, in some places to 1500 m.

**Food and Feeding.** Diet not documented. Usually occurs singly or in pairs; often in mixed-species flocks. Forages in dense lower strata, 1-7 m above the ground; hops about, taps on dead and live twigs.

**Breeding.** Season Jan-Mar in Peru and Bolivia, probably later in Ecuador. No other information.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Fairly common in Colombia; rare to locally uncommon in Ecuador; uncommon in Peru. Probably overlooked owing to inconspicuous behaviour; may be more common than believed. Occurs in Amacayacu National Park (Colombia); also present in Manu National Park and Tambopata Reserve (Peru).

**Bibliography.** Angehr & Aucca (1997), Brace *et al.* (1997), Butler (1979), Clements & Shany (2001), Donahue (1994), Guilherme (2001), Hilty & Brown (1986), Kratter (1997), Munn (1985), Norton (1965), Parker *et al.* (1982), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Greenfield (2001), Ridgely *et al.* (1998), Robinson & Terborgh (1997), Rodner *et al.* (2000), Ruschi (1979), Sick (1993), Stotz *et al.* (1996), Terborgh *et al.* (1984).

PLATE 25

## 22. Tawny Piculet

### *Picumnus fulvescens*

**French:** Picumne fauve

**German:** Fahlzweragspecht

**Spanish:** Carpinterito Canela

**Taxonomy.** *Picumnus fulvescens* Stager, 1961, Garanhuns, south-eastern Pernambuco, Brazil. Probably related to *P. limae*, and sometimes even regarded as conspecific, but may perhaps be closer to *P. nebulosus*. Form *saturatus*, described from Paraíba and previously listed as a race of *P. limae*, is now considered a junior synonym of *fulvescens* (see page 302), which has priority by merely one day. Monotypic.

**Distribution.** NE Brazil, from E Piauí through S Ceará to Paraíba, Pernambuco and Alagoas.

**Descriptive notes.** 10 cm. Male has top of head black, crown feathers broadly tipped red and forming almost solid patch, rest spotted white; white or buffish-white lores, nasal tufts and upper moustachial region, whitish line behind eye, dark brown ear-coverts obscurely pale-streaked; rusty-buff hindneck and neck sides; upperparts unmarked brown to rufous-brown or tinged yellowish-brown, uppertail-coverts paler, dark brown upperwing and wing-coverts narrowly edged and tipped paler; uppertail brownish-black, central feather pair with broad white stripe on inner webs, outer 2 pairs with diagonal white subterminal area; chin and

throat variably whitish to buff or buffish-brown; rest of underparts light yellow-brown to rufous or rusty, breast with indistinct whitish shaft streaks, streaks broader and more cinnamon-toned on flanks and belly; underwing pale brown, coverts yellowish-brown to rusty; bill short, pointed, culmen slightly curved, black with pale grey base; iris dark brown, orbital ring greyish; legs grey. Female has entire top of head spotted white; underparts may be more heavily streaked on average. Juvenile undescribed. Voice. Call a descending series of "driée driée driée...".

**Habitat.** Inhabits deciduous, semi-deciduous and secondary stands in the Atlantic forest; also found in degraded secondary scrub, and edges; to lesser extent also *caatinga*. Recorded from lowlands up to c. 950 m.

**Food and Feeding.** No information.

**Breeding.** Undocumented.

**Movements.** Presumably resident.

**Status and Conservation.** VULNERABLE. Restricted-range species: present in North-east Brazilian Caatinga EBA and Atlantic slope of Alagoas and Pernambuco EBA. Scarce. Known range covers only 470 km<sup>2</sup> in 5 states; has been recorded from no more than 10 localities, and has probably already disappeared from some of those. Most of its habitat in the Atlantic forest has been destroyed, mainly through logging and conversion to commercial plantations and pasture; the little remaining is fragmented, greatly threatened by fires and also subject to continuing exploitation, with new roads being built in 1999. Distribution in *caatinga* little known, but expansion of agriculture, along with burning and grazing, has also destroyed much suitable habitat there. Recorded in five protected areas: at one of these, Pedra Talhada Biological Reserve (Alagoas), reforestation with indigenous trees has been supported by local inhabitants, and area is patrolled by official guards to prevent illegal activities; other sites with formal protection are Serra da Capivara National Park, Serra Negra Biological Reserve, Tapacurá Ecological Station and Araripe National Forest. Chapada do Araripe, in S Ceará, seems to be another important site for the species. Regular occurrence of species in degraded scrub and edge habitat may indicate potential adaptability. Recommendations include survey work to establish its exact distribution, status and ecology, and effective protection of all sites where it occurs.

**Bibliography.** Bañuelos-Irusta *et al.* (2000a, 2000b), Collar *et al.* (1994), Forrester (1993), Lima (2001), do Nascimento (2000), do Nascimento *et al.* (2000), Olrog (1968), Pinto & Camargo (1961), Ruschi (1979), Sick (1993), Stager (1961b), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Teixeira (1990), Wheatley (1994).

## 23. Ochraceous Piculet

### *Picumnus limae*

**French:** Picumne ocré

**German:** Ockerzweragspecht

**Spanish:** Carpinterito de Ceará

**Taxonomy.** *Picumnus limae* Sneath, 1924, Serra de Maranguape, Ceará, Brazil.

Probably related to *P. fulvescens*, and sometimes regarded as conspecific. Form *saturatus*, described from Paraíba and previously listed as a race of present species, is now considered a junior synonym of *P. fulvescens* (see page 302). Monotypic.

**Distribution.** NC Ceará in NE Brazil.

**Descriptive notes.** 10 cm. Male has top of head black, crown with broad red feather tips forming almost solid patch, rest spotted white; white lores and nasal tufts, white line behind eye, pale rusty-brown ear-coverts; greyish-brown hindneck and upperparts with yellowish-rusty wash, dark brown upperwing and wing-coverts edged and tipped pale to buffish; secondaries and tertials more broadly pale-edged; uppertail dark brown, central feather pair with broad white or buff-white stripe on inner webs, outer 2 pairs with diagonal white subterminal area; neck side, malar, chin and entire underparts white, with buff or pale yellow tinge especially on lower underparts, occasionally faint fine barring in malar and chin region, sometimes very faint trace of bars on belly and flanks; underwing pale brown, coverts whitish; bill short, culmen curved, blackish with greyish-horn base of lower mandible; iris deep brown, orbital skin

greyish; legs blue-grey. Female has entire top of head spotted white. Juvenile apparently undescribed. Voice. High-pitched "sirr-sirr-sirr", recalling hummingbird (Trochilidae).

**Habitat.** Semi-deciduous forest and adjacent tall *caatinga* on hillsides, at up to 1000 m; also forages occasionally in degraded scrub or edge with exotic bamboo and abandoned orchards, but this thought probably unusual.

**Food and Feeding.** No information.

**Breeding.** No details known.

**Movements.** Presumably resident.

**Status and Conservation.** VULNERABLE. Has tiny range, within which it is known from only three sites: Serra do Ibiapaba, Serra do Baturité and Serra do Arataruá. Fairly common locally, but very few recent records. Potentially suitable habitat has been greatly reduced through agricultural expansion, grazing and burning, with forest virtually completely destroyed in some areas; in Serra do Baturité, for example, clearance for coffee plantations since early 1970's has resulted in loss of 99% of original forest habitat. Remaining habitat is also under threat from construction of holiday homes, as well as fires. A protected area was established in the Serra do Baturité in 1991, but whether this has led to surviving forest being preserved is unclear; some areas of habitat are protected by hotel-owners in the region. Preferred habitats are not typical of the *caatinga* dry zone inhabited by this species, suggesting that it is dependent on specific habitat types. Investigation of the species' precise distribution, status, habitat requirements and general ecology is urgently needed, together with full protection of all sites where it is found.

**Bibliography.** Collar *et al.* (1994), Lima (2001), Meyer de Schauensee (1982), Pinto & Camargo (1961), Ruschi (1979), Sargeant & Wall (1996), Sick (1993), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Teixeira (1990), Wheatley (1994), Willis (1992).

## 24. Mottled Piculet

### *Picumnus nebulosus*

**French:** Picumne strié

**German:** Braunbrust-Zweragspecht

**Spanish:** Carpinterito Uruguayo

**Taxonomy.** *Picumnus nebulosus* Sundevall, 1866, southern Brazil.

Possibly related to *P. fulvescens*. Monotypic.

**Distribution.** SE Brazil (Paraná S to Rio Grande do Sul), marginally NE Argentina (E Corrientes), and Uruguay (except W & SW).

**Descriptive notes.** 10-11 cm; 11-12 g. Male has black forehead to nape, feathers of upper forehead and crown with broad red tips often forming patch, crown sides and nape tipped white; white lores; rather dark olive-brown cheeks and lower ear-coverts, large but irregular white area on upper ear-coverts; neck side buffy olive-brown; warm olive-brown hindneck and upperparts tinged buff or rusty on back and scapulars; dark brown to blackish upperwing and wing-coverts with broad pale margins, broadest and palest on secondaries and tertials; uppertail black, central feather pair with white stripe on inner webs, outer 3 pairs

with white streak on outer webs; malar, chin and throat white, thinly barred black; rusty buffish-brown breast sometimes with faint dark streaks, paler buff belly and usually richer buff flanks, with broad blackish streaks, spots or U-shaped bars from lower breast to flanks; underwing pale brownish, coverts rusty-buff; bill short, straight, slightly chisel-tipped, black with grey base of lower mandible; iris brown, orbital skin greyish; legs grey. Female has entire top of black head spotted white. Juvenile duller than adults, dull brown crown streaked pale buffish. Voice. Humming "tseswret, si-si-si"; series of weak single squeaks by juvenile as contact with parent; drums loudly on bamboo, short pauses between bursts of 2-4 strokes, sound resembling that of some frogs (*Strombus*).

**Habitat.** Inhabits forest, mostly lowland evergreen forest and mixed *Araucaria* forest with dense understorey, also forest edge, gallery woodland; often in areas with bamboo. Occurs from lowlands up to 1100 m; in SE Brazil, recently recorded at 1400 m in Jun in Santa Catarina.

**Food and Feeding.** Diet not documented. Hunts singly; joins mixed-species flocks. Forages at low levels on slender woody stems, particularly dead bamboo, also in dense scrub, including roadside scrub; also to at least 7-8 m above ground, working along thin branches.

**Breeding.** Season Oct-Dec. No other information.

**Movements.** Mainly resident; some altitudinal movements may occur.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Generally local and uncommon; more common in S part of Brazilian range; very few recent records from Argentina. Occurs in Aparados da Serra National Park in Brazil. Has for many years suffered from habitat loss and degradation, with lowland forest in species' range cleared for agricultural and other purposes, including mining; most serious of current threats are urbanization, industrialization, continuing expansion of agriculture, and human colonization accompanied by further road-building. The few areas of remaining forest known to harbour this species in Argentina would be flooded if proposed Garabí dam is built on the R Uruguay.

**Bibliography.** dos Anjos (1999), dos Anjos & Schuchmann (1997), dos Anjos *et al.* (1997), Belton (1984), Bencke & Kindel (1999), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Meyer de Schauensee (1982), Naka *et al.* (2000), Narosky & Yzurieta (1993), Olrog (1968), Parker & Goerck (1997), de la Peña (1994), do Rosário (1996), Ruschi (1979), Sick (1993), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993).

## 25. Plain-breasted Piculet

### *Picumnus castelnau*

**French:** Picumne de Castelnau

**German:** Gelbbauch-Zweragspecht

**Spanish:** Carpinterito Blancuzco

**Taxonomy.** *Picumnus castelnau* Malherbe, 1862, Sarayacu, Ecuador.

Possibly close to *P. subtilis*, with which may occasionally hybridize. Monotypic.

**Distribution.** SE Colombia (SE Amazonas) and S in E Peru to Pucallpa, on R Ucayali; old specimens supposedly from E Ecuador considered to have originated from elsewhere.

**Descriptive notes.** 8-9 cm; 11-12 g. Male has black forehead to nape, central crown with broad red feather tips, lower nape finely vermiculated whitish; buffish-white lores and nasal tufts, whitish streak above eye; brown ear-coverts vermiculated grey and whitish; olive-brown rear superciliary area, hindneck and neck sides barred or vermiculated buff-grey; dark greyish-olive upperparts sometimes indistinctly barred paler, wing-coverts edged and tipped yellow-green; dark brown flight-feathers edged paler, tertials more broadly margined brighter yellow; uppertail dark brown, white stripe on inner webs of central feather pair and on outer

3 pairs; moustachial and malar area, chin and throat pale yellowish-white, moustache sometimes faintly barred near bill; rest of underparts white, lightly washed yellowish, breast sides, belly and flanks occasionally with some almost invisible darker bars; underwing grey-brown, coverts white; short bill pointed, culmen curved, black with pale blue-grey to whitish base of lower mandible; iris dark brown, orbital ring buff-grey; legs greyish. Distinguished from *P. subtilis* by redder crown tips, lack of white nape spots, paler unbarred underparts. Female has unmarked black crown. Juvenile like adult female, but duller, with stronger hint of barring above, faint barring below. Voice. Very high-pitched, thin trill, "t'e'e'e'e'e'e", dropping in pitch and amplitude at end.

**Habitat.** Swamp-forest, várzea forest, and forest edge near water; especially favours well-developed second growth dominated by *Cecropia* and *Mimosa*. Lowlands to 900 m.

**Food and Feeding.** Diet not recorded. Hunts solitarily or in pairs; regularly joins mixed-species flocks in Peru, more rarely so in Colombia. Forages in lower parts of the canopy and down to understorey; taps on dead branches, often spending lengthy time at favoured spots.

**Breeding.** Female feeding fledgling in mid-Jun in Colombia; season probably May-Jul. No further details available.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Comparatively rare overall, though possibly commoner than it appears to be, as it is rather inconspicuous. Generally uncommon and local in Peru, but locally not uncommon near Iquitos, around Explornapo and Explorama Lodges. Occurs in Amacayacu National Park in Colombia.

**Bibliography.** Butler (1979), Clements & Shany (2001), Hilty & Brown (1986), Meyer de Schauensee (1982), Otrog (1968), Parker *et al.* (1982), Remsen (1977), Ridgely & Greenfield (2001), Rodner *et al.* (2000), Stotz *et al.* (1996), Wheatley (1994).

## 26. Fine-barred Piculet

### *Picumnus subtilis*

**French:** Picumne de Cuzco **German:** Cuzcozwerpspecht **Spanish:** Carpinterito de Cuzco  
**Other common names:** Marcapata/Stager's Piculet

**Taxonomy.** *Picumnus subtilis* Stager, 1968. Hacienda Villacarmen, Cuzco, south-eastern Peru. Possibly close to *P. castelnaui*, with which may occasionally hybridize. Monotypic.

**Distribution.** E Peru, from R Ucayali in Loreto S to Cuzco (Marcapata).

**Descriptive notes.** 10 cm; 10-11 g. Male has black forehead to nape, feathers of upper forehead and crown tipped orange-red, crown sides and nape spotted white; pale buff-white lores and nasal tufts; brownish-olive ear-coverts barred whitish; pale olive-buff neck sides vermiculated darker; yellowish-green hindneck and upperparts with obscure olive barring, dark olive-brown wing-coverts edged yellow-green; dark brown flight-feathers narrowly margined yellowish-green, outer webs of secondaries with broader pale edges; uppertail dark brown, central feather pair with broad white stripe on inner webs, outer 2 pairs

with narrower white subterminal area; pale buffish malar barred olive, pale greyish-buff chin and throat occasionally finely olive-banded; breast light olive-grey with fine olive barring or vermiculation, belly and flanks paler yellow to buff-grey with bars usually less distinct (or absent on belly); underwing pale brownish, coverts largely white; bill short, culmen curved, black with blue-grey base of lower mandible; iris brown, orbital skin greyish; legs olive, tinged green. Female has black crown with white spots. Juvenile more heavily barred than adults, but barring below more diffuse. Voice. Apparently not described.

**Habitat.** Humid tropical forests. From lowlands to Andean foothills at 1000 m.

**Food and Feeding.** No information.

**Breeding.** No definite information; season probably Apr-Jul.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in South-east Peruvian Lowlands EBA. Rare and little known. Occurs at Amazonia Lodge. Formerly considered Near-threatened, this species' conservation status may merit further reassessment.

**Bibliography.** Clements & Shany (2001), Collar *et al.* (1994), Parker *et al.* (1982), Schiffer (2000), Stager (1968), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wheatley (1994).

## 27. Olivaceous Piculet

### *Picumnus olivaceus*

**French:** Picumne olivâtre **German:** Olivrücken-Zwerpspecht **Spanish:** Carpinterito Oliváceo

**Taxonomy.** *Picumnus olivaceus* Lafresnaye, 1845. Bogotá, Colombia.

Forms a superspecies with *P. granadensis*, and possibly conspecific. Proposed race *panamensis* (E Panama to extreme NW Colombia) considered insufficiently distinct from *flavotinctus*, and *malleolus* (N Colombia from N Sucre S to upper R Sinú and S Bolívar) not distinguishable from nominate. In past, race *eisenmanni* was referred to as race "*perijanus*", but this name is preoccupied by a race of *P. cinnamomeus*. Six subspecies currently recognized.

### Subspecies and Distribution.

*P. o. dimotus* Bangs, 1903 - E Guatemala, N Honduras and E Nicaragua.

*P. o. flavotinctus* Ridgway, 1889 - Costa Rica, Panama and extreme NW Colombia (N Chocó).

*P. o. eisenmanni* Phelps, Jr. & Avelledo, 1966 - Sierra de Perijá in extreme NW Venezuela, possibly also in adjacent N Colombia.

*P. o. olivaceus* Lafresnaye, 1845 - W Colombia from N Sucre (Serranía de San Jacinto) S to upper R Sinú and S Bolívar, S in C Andes to lower Cauca Valley and in E Andes to Huila.

*P. o. tachirensis* Phelps, Sr. & Gilliard, 1941 - E slope of E Andes in NC Colombia (Norte de Santander) and adjacent SW Venezuela (SW Táchira).

*P. o. harterti* Hellmayr, 1909 - SW Colombia (SW Nariño) and W Ecuador; recently recorded in NW Peru (Tumbes).

**Descriptive notes.** 8.5-10 cm; 10-15 g. Male has black forehead to nape, feathers of upper forehead and crown tipped red, hindcrown and nape spotted white; whitish lores; brown cheeks and ear-coverts, feathers below and behind eye tipped white; neck sides light yellowish-brown; olive-brown upperparts tinged yellow, wing-coverts narrowly edged yellowish; dark brown flight-feathers with prominent yellow to yellow-green edges; uppertail brown, central feather pair with pale buff or yellowish stripe on inner webs, outer 2 pairs with diagonal stripe; malar, chin and throat buff to yellowish-white, narrow dark feather edges

producing scaly pattern; breast yellowish-brown, lower underparts paler buffish-white to dull yellowish, belly and, especially, flanks with broad brownish streaks but variable; underwing brownish-grey, coverts whitish; bill short, culmen slightly curved, black with greyer base of lower mandible; iris dark brown, orbital skin grey to blue-grey; legs grey, often tinged blue or green. Distinguished from *P. granadensis* by paler yellow upperparts, darker underparts, red crown spots of male. Female has entire top of head dotted white. Juvenile duller and browner than adults, sometimes paler and more heavily streaked below. Races differ relatively little from nominate: *dimotus* green-tinged above, paler below, breast more olive, male crown tips yellow-orange; *flavotinctus* dark olive to olive-green above, more olive-toned below, male crown tips yellow; *eisenmanni* distinctly yellowish above, more yellow in wings, pale yellowish-olive breast, yellow belly, male crown tips orange to yellow; *tachirensis* green-tinged above, male crown tips orange to yellow; *harterti* rather small, generally darker olive, male crown tips yellow to golden. Voice. Fine, rapid twitter or trill, soft and clear by partner arriving at hole, shrill and insect-like in self-announcement, suggesting song of Yellow-faced Grassquit (*Tiaris olivacea*) or Worm-eating Warbler (*Helminthophila vermivorus*); sharp sibilant "sst, ssip-ssip" or "peep", sometimes repeated, e.g. by fledglings responding to parents' trills; nestlings utter continuous buzz.

**Habitat.** Wide variety of habitats, including borders of humid rainforest and cloudforest (apparently avoiding mature stands), also drier forest, semi-open and open woodland, overgrown shrubby clearings, second growth, and cultivated land at dense forest edge with many creepers; also shady plantations and gardens. Most frequent in lowlands and foothills, but occurs also at higher elevations: to 500 m in Guatemala to Honduras; to 1400 m in Costa Rica; mostly below 1200 m in Panama but to 1600 m on Pacific slope (Chiriquí); 800-2300 m in Venezuela; to 1800 m, rarely to 2500 m, in Colombia; mainly below 900 m in Ecuador. Replaced by *P. granadensis* in W Andes.

**Food and Feeding.** Primarily ants (e.g. *Camponotus*, *Pseudomyrmex*, *Crematogaster*) and termites, including larvae and pupae; also beetles, and cockroach (Blattodea) eggs. Hunts singly, in pairs, or in family groups of 4-5 birds; frequently joins mixed-species flocks. Forages mainly at lower and middle heights in undergrowth, open thickets and low tangles, occasionally also in tree-tops; creeps up and down, often perches crosswise, many movements recall a nuthatch (*Sitta*) or xenops (*Xenops*); investigates thin branches, fine twigs and vines, apparently avoiding trunks and large limbs of tall trees. Drills tiny holes by very rapid hammering in thin branches to reach ant nests; extracts ant brood and gleans the adults. Also gleans insects from dead twigs and vines; pecks in petioles of large leaves, including fallen ones and those caught up in vines or branches, and extracts grubs.

**Breeding.** Dec-May in Costa Rica and Panama, and Feb-Sept in Colombia; often double-brooded. Nest excavated by both sexes at 0.9-9 m, mostly below 2 m, in slender stub with very soft wood, or in rotting post near thicket; circular entrance 2.2-2.5 cm in diameter, cavity 5-6 cm at widest point, 9-10 cm deep; excavation takes c. 1-4 weeks, but sometimes only 4-5 days. Clutch 2 or 3 eggs, but usually no more than 2 young reared; both parents sleep in nest before egg-laying and also during incubation; both also incubate, male apparently taking greater share, period 13-14 days; chicks fed by both parents, sometimes more by male; in one study, hourly feeding rate per chick was 1-3 at 7 days, 4-5 at 14 days, 1-6 at 22 days; young leave nest after 24-25 days; fledglings roost with both parents in nest for 4-16 weeks, remaining during incubation of second brood, at least until hatching.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to uncommon in Guatemala to Honduras; uncommon to fairly common in Costa Rica; uncommon and rather local in Panama, but more widespread and numerous in E; uncommon in Colombia; uncommon to fairly common in Ecuador. Occurs in several protected areas, e.g. Corcovado National Park (Costa Rica) and Río Palenque Science Centre (Ecuador).

**Bibliography.** Anon. (1998b), Becker & López (1997), Clements & Shany (2001), Fjeldså & Krabbe (1990), Haffer (1975), Hilty (1997), Hilty & Brown (1986), Howell & Webb (1995), Land (1970), Meyer de Schauensee & Phelps (1978), Monroe (1968), Otrog (1967), Parker *et al.* (1995), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Robbins *et al.* (1985), Rodner *et al.* (2000), Skutch (1948b, 1969a, 1998), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a).

## 28. Greyish Piculet

### *Picumnus granadensis*

**French:** Picumne gris **German:** Braunrücken-Zwerpspecht **Spanish:** Carpinterito Colombiano

**Taxonomy.** *Picumnus granadensis* Lafresnaye, 1847. Cali, Colombia.

Forms a superspecies with *P. olivaceus*, and possibly conspecific. Two subspecies recognized.

### Subspecies and Distribution.

*P. g. antioquiensis* Chapman, 1915 - W Andes in NW Colombia, from Antioquia S, on W slope, to upper R San Juan.

*P. g. granadensis* Lafresnaye, 1847 - C Cauca Valley S to upper Patía Valley.

**Descriptive notes.** 9-10 cm; 12-13 g. Male has black forehead to nape, crown feathers finely tipped yellow, rest tipped white; white lores; chestnut-brown ear-coverts sometimes with few white streaks;

grey-brown neck sides often with some white spots or streaks; greyish-brown hindneck and upperparts often tinged olive, dark brown upperwing and wing-coverts edged yellowish-green; uppertail dark brown, central feather pair with broad white stripe on inner webs, outer 2 pairs with diagonal subterminal white stripe; cheeks, malar, chin and throat off-white with narrow blackish feather tips; grey-brown of neck sides extending slightly onto breast sides, rest of underparts dull white, sometimes very fine greyish streaks on flanks; underwing pale brownish, coverts grey and white; bill short, culmen curved, black; iris brown, orbital skin

grey-blue; legs grey, tinged blue or green. Differs from *P. olivaceus* in less olive tone above, much paler underparts, smaller and yellow crown tips of male. Female has white-spotted crown. Juvenile duller, darker than adults, greyish and streaked below. Race *antioquiensis* has greyer upperparts, more obvious grey streaking on belly and flanks. VOICE. Calls infrequently, a high-pitched weak trill on one pitch.

**Habitat.** Edges of dry to moderately humid forest, second growth, scrub and woodland, at 800-2100 m, possibly down to 600 m in N of range. Replaces *P. olivaceus* in W Andes.

**Food and Feeding.** No details; presumably similar to *P. olivaceus*.

**Breeding.** Season apparently Jan to about Jun. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Colombian Inter-Andean Valleys EBA. No data on numbers; uncommon.

**Bibliography.** Fjeldså & Krabbe (1990), Hilty & Brown (1986), Meyer de Schauensee (1982), Miller (1963), Olrog (1968), Rodner *et al.* (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vélaz & Velázquez (1998), Wheatley (1994).

## 29. Chestnut Piculet

### *Picumnus cinnamomeus*

**French:** Picumne cannelle **German:** Zimtzwergspecht **Spanish:** Carpinterito Castaño

**Taxonomy.** *Picumnus cinnamomeus* Wagler, 1829, Cartagena, north Colombia.

Four subspecies recognized.

**Subspecies and Distribution.**

*P. c. cinnamomeus* Wagler, 1829 - coastal N Colombia, S locally to lower Cauca Valley (R Nechí) and lower Magdalena Valley.

*P. c. persaturatus* Haffer, 1961 - Serranía de San Jerónimo, in Bolívar (NC Colombia).

*P. c. perijanus* J. T. Zimmer & Phelps, Sr., 1944 - N shores of L Maracaibo (NW Venezuela).

*P. c. venezuelensis* Cory, 1913 - S & E shores of L Maracaibo (W Venezuela).

**Descriptive notes.** 9-10 cm. Very distinctive piculet. Male has pale creamy forehead, lores and nasal tufts, black crown to nape, crown feathers tipped yellow, nape feathers tipped white; rest of body plumage deep rufous to rusty-brown, rump and belly a shade paler; upperwing and wing-coverts dark brown, edged and tipped cinnamon to rufous; uppertail brownish-black, central feather pair with broad pale cinnamon stripe on inner webs, outer 2 pairs with stripe on outer webs; underwing grey-brown, coverts rufous; bill short, stout, culmen slightly curved, blackish; iris brown, orbital skin yellow; legs grey. Female lacks yellow on crown, white spots

confined to hindcrown and nape. Juvenile apparently undescribed. Race *persaturatus* is darker, more chestnut, than nominate, has brighter wing edgings, more obscurely patterned tail, female crown fully white-spotted; *perijanus* is similar to previous, but not quite so dark, female with crown much more heavily spotted; *venezuelensis* is as dark as first, has cinnamon-tawny forehead, female crown spotted white but nape unspotted. VOICE. Apparently undescribed.

**Habitat.** Wide range of habitats, from rainforest, humid coffee plantations, and deciduous forest, to open terrain with scattered trees, borders of dry forest, and arid and semi-arid scrub; also mangroves in Colombia; particularly favours thorny woodland. From sea-level to 100 m in Venezuela, to 300 m in Colombia.

**Food and Feeding.** Diet apparently not documented; probably takes ants and other small insects. Observed singly, in pairs, sometimes in small family groups; joins mixed-species groups. Tends to forage in dense thickets and vine tangles; forages at virtually all levels. Very active, not shy; hops through thickets, creeps like a nuthatch (*Sitta*) over trunks and branches.

**Breeding.** Laying in Dec and juvenile seen in Mar in Colombia. No other details documented.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Caribbean Colombia and Venezuela EBA. Common in Colombia; probably common locally in Venezuela, but few records. Considering that this species is not so inconspicuous as most other piculets, it is rather poorly known.

**Bibliography.** Haffer (1975), Hilty & Brown (1986), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Rodner *et al.* (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wheatley (1994), Zimmer & Phelps (1944).

## Genus SASIA Hodgson, 1836

## 30. African Piculet

### *Sasia africana*

**French:** Picumne de Verreaux **German:** Graubauch-Mausspecht **Spanish:** Carpinterito Africano

**Other common names:** Pygmy Wood Piculet, Pygmy Woodpecker(!)

**Taxonomy.** *Sasia africana* J. Verreaux and E. Verreaux, 1855, Gabon.

Sometimes placed in monotypic genus *Verreauxia*, but appears close to *S. abnormis* and *S. ochracea*. Monotypic.

**Distribution.** S Cameroon and SW Central African Republic E to SW Uganda (Bwamba Forest), S to NW Angola (S to Cuanza Norte, N Lunda Norte) and SC & SW Zaire; a few isolated records in recent decades from Liberia, Ivory Coast and Ghana indicate existence of a small population in forests of Upper Guinea.

**Descriptive notes.** 9-10 cm; 7.5-10.5 g. The only African piculet. Male has chestnut to rufous forehead, olive-green to greyish-olive crown to hindneck; blackish lores, thin blackish stripe behind eye bordered above by short white line; rest of head rather dark grey, often streaked darker on ear-coverts, which have white crescent at lower rear border; entire upperparts dark green, tinged yellow, uppertail-coverts duller; wing-coverts, secondaries and tertials sometimes slightly darker, but with brighter yellow fringes; brownish-black primaries with whitish on inner webs, narrowly edged and tipped yellow on outer webs; extremely

short tail with 8 (not 10) brownish-black feathers edged olive-greenish; chin and throat dark olive-grey, rest of underparts darkish grey with slight to strong olive tinge, belly often paler; underwing mostly whitish; bill short, culmen curved, black with paler lower mandible; iris red, orbital skin light red to pale purple-red or pinkish-purple; legs reddish to purple-red. Female slightly longer-winged, lacks chestnut on forehead. Juvenile has rufous feather tips on head, especially ear-coverts, and on throat, belly and flanks, grey and buffy tones admixed in mantle and back, brown iris. VOICE. Weak high trill, "ti-ti-ti-ti-ti-ti".

**Habitat.** Inhabits humid forest, mainly in ecotone between primary and secondary growth, also gallery forest; prefers old second growth to open primary forest. Occurs from lowlands to c. 700 m, locally up to 1000 m.

**Food and Feeding.** Principal food made up of wood-boring beetle larvae; also consumes adult beetles and other insects, but appears not to take ants. Commonly encountered in pairs or trios; occasionally joins mixed-species flocks. Forages mainly in lower storeys; constantly on the move, hops and flies rapidly through dense vegetation. Forages in bushes, also clings to stems of larger herbaceous plants and grass. Hammers vigorously into the substrate, splitting it open to get at prey.

**Breeding.** Laying dates span Jun-Feb; juvenile collected in Mar in Angola. Nest excavated 1.5 m above ground in narrow branch, entrance 2 cm across, cavity dimensions c. 4 x 5 cm. Clutch usually 2 eggs; both parents incubate eggs and tend brood, periods unknown.

**Movements.** Essentially resident. Several records from Upper Guinea, including two from Liberia, one from Ivory Coast, two from Ghana, and possibly one from Nigeria, have been suggested as pointing to abnormal long-distance dispersal, but much more likely to refer to small, sparse populations.

**Status and Conservation.** Not globally threatened. Locally common, e.g. in parts of Gabon; common in Bwamba Forest in Uganda; not uncommon in Angola. Occurs at Mount Kupé and in Korup National Park in Cameroon. Although this species has been considered generally uncommon, its habits make it likely to be overlooked; in much of range, it seems to be reasonably common in secondary forest. No immediate threats known.

**Bibliography.** Bannerman (1953), Bowden (2001), Christy & Clarke (1994), Dean (2000), Delacour (1951a), Demey & Fishpool (1991, 1994), Dowsett (1989b), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1999, 2000), Dowsett-Lemaire *et al.* (1993), Fjeldså & Jensen (1990), Fry *et al.* (1988), Gatter (1988), Germain & Cornet (1994), Grimes (1987), Lippens & Wille (1976), Louette (1981b), Macdonald & Taylor (1977), Mackworth-Præd & Grant (1962, 1970), Pinto (1983), Rand *et al.* (1959), Sargeant (1993), Short (1971d, 1980, 1985b), Snow (1978), Thiollay (1985b).

## 31. Rufous Piculet

### *Sasia abnormis*

**French:** Picumne roux **German:** Malaïenmausspecht **Spanish:** Carpinterito Malayo

**Taxonomy.** *Picumnus abnormis* Temminck, 1825, Java.

Two subspecies recognized.

**Subspecies and Distribution.**

*S. a. abnormis* (Temminck, 1825) - S Myanmar (Tenasserim) and adjacent SW Thailand, S to Sumatra (including Belitung I), Borneo and W & C Java.

*S. a. magnirostris* Hartert, 1901 - Nias I. off NW Sumatra.

**Descriptive notes.** 9 cm; 7.2-12 g. Male has yellow forehead, sometimes with rufous admixed, yellowish-olive crown to hindneck; remainder of head and neck rufous to orange-rufous, generally darker on ear-coverts; upperparts yellowish-olive, rump partly or wholly rufous, uppertail-coverts black; olive-brown wing-coverts, secondaries and tertials edged yellow; primaries brown, inner webs edged rufous, outer webs sometimes edged dark rufous; uppertail (10 feathers) very short, black, edged dull olive; entire underparts rufous, flanks usually washed yellow; underwing whitish, with pale rufous or cinnamon primary

patch; relatively long bill curved on culmen, grey to brown with yellow lower mandible; iris red to orange-rufous, orbital skin dark red to purplish; legs dull yellow to orange, only 3 toes. Distinguished from *S. ochracea* by lack of white rear supercilium, more olive upperparts without rufous tones, yellow lower mandible. Female has slightly larger bill, wing and tail, all-rufous forehead. Juvenile darker than adults, has head and underparts mostly slate-brown, mantle washed slate-grey, all-dark bill, brown iris. Race *magnirostris* differs from nominate only in having longer, deeper bill. VOICE. Single sharp "tsit" or "tic", usually repeated; high-pitched rapid "kih-kih-kih-kih-kih" or "kik-ik-ik-ik-ik-ik" by territorial male; alarm "kip, kip, kip"; drums loudly, a fast rattle slowing to paired beats, rolls c. 1-1.5 seconds in duration.

**Habitat.** Secondary forest with old decaying trees, swamp-forest, to lesser extent primary forest; much prefers dense second growth, particularly bamboo stands, and other low dense vegetation. Often found near water. Lowlands and hills to 800 m, to 1370 m in Malay Peninsula.

**Food and Feeding.** Ants and their larvae, and small bark beetles (Scolytidae); soft insects and their larvae; also spiders. Hunts singly, or in family parties of 3-5 individuals; often joins mixed-species flocks. Forages at low and middle levels, generally no higher than 5 m above ground; moves very rapidly through dense vegetation, often flies longer distances from one spot to another rather than proceeding steadily from tree to tree. Inspects bamboo, thin trunks, dead branches, vines, shrubs and saplings, also feeds among grasses in the understorey. Often perches crosswise, and moves upwards in short flights. Foraging techniques include persistent quiet pecking, and gleaning; reaches ants in bamboo stems by excavating small holes, then inserting the long tongue to obtain prey.

**Breeding.** May-Aug; from Feb in Borneo. Nest excavated low down in dead branch, sapling or bamboo stem; 2 nest-holes in Peninsular Malaysia were less than 1 m from ground, entrance less than 2.5 cm wide. Clutch usually 2 eggs, possibly sometimes 3; incubation and fledging periods unrecorded; young remain with parents for some time after leaving nest. Maximum recorded longevity at least 7 years 2 months.

**Movements.** Resident. In ringing studies in Malaysia, two females retrapped after several years only 800 m from ringing site.

**Status and Conservation.** Not globally threatened. Fairly common to common in Myanmar, Thailand, Sumatra and Borneo; common in Peninsular Malaysia, but absent from Singapore. Occurs in several protected areas within its range, including Khao Nor Chuchi Non-hunting Area (Thailand), Taman Negara National Park and Panti Forest Reserve (Malaysia), and Way Kambas National Park (Sumatra). Difficult to observe, and possibly overlooked. Appears reasonably adaptable, and preference for secondary habitats suggests that it is not likely to be threatened in near future.

**Bibliography.** Andrew (1992), Baker (1919), van Balen (1999), Bromley (1952), Delacour (1951a), Duckworth & Kelsh (1988), Duckworth *et al.* (1997), Hellebrekers & Hoogerwerf (1967), Holmes (1994), Jeyarajasingam & Pearson (1999), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Philipps (1993), Madoc (1976), van Marle & Voous (1988), Medway & Wells (1976), Riley (1938), Robinson (1928), Robson (2000), Short (1973d), Smythies (1986, 1999), Vowles & Vowles (1997), Wells (1985, 1999), Wilkinson, Dutson & Sheldon (1991), Wong (1985).

## 32. White-browed Piculet

### *Sasia ochracea*

**French:** Picumne à sourcils blancs **German:** Rötelausspecht **Spanish:** Carpinterito Cejiblanco  
**Other common names:** Himalayan Rufous Piculet (*ochracea*); Burmese Rufous Piculet (*reichenowi*)

**Taxonomy.** *Sasia ochracea* Hodgson, 1836, Nepal.

Race *hasbroucki*, described from S Myanmar and S Thailand, is synonymous with *reichenowi*. Birds from S Assam, Bangladesh and SW Myanmar sometimes separated as race *querulivox* on basis of paler coloration, but this matched by individuals from SE Asia. Three subspecies recognized.

#### Subspecies and Distribution.

*S. a. ochracea* Hodgson, 1836 - N India (N Uttar Pradesh) and C Nepal E to N & C Thailand and Vietnam.

*S. o. kinneari* Stresemann, 1929 - extreme N Vietnam (Tonkin) and adjacent S China (Yunnan, Guangxi).

*S. a. reichenowi* Hesse, 1911 - S Myanmar (Tenasserim) and SW Thailand S to Isthmus of Kra.

**Descriptive notes.** 9-10 cm; 8.3-11.8g. Male has rufous to orange-rufous forehead and forecrown, with bright golden-yellow patch in centre of forehead; rest of crown to hindneck olive-green, variably tinged rufous; white stripe behind eye; rufous to cinnamon-rufous lores, cheeks and sides of neck, darker ear-coverts; upperparts green with variable element of rufous, rump (sometimes also mantle and back) mainly rufous, uppertail-coverts blackish; brown upperwing and wing-coverts edged and tipped green to yellow-green, primaries edged buffish on inner webs; uppertail (10 feathers) very short, brownish-black, feathers narrowly edged greenish; entire underparts varying from deep rufous to lighter rufous, sometimes hint of yellowish on breast and flanks; underwing mostly buffish-white; bill shortish, culmen curved, black upper mandible, grey lower mandible; iris red, orbital skin pinkish-red; legs orange or yellow-orange, only 3 toes. Distinguished from *S. abnormis* by white stripe behind eye, rufous tones above, darker lower mandible. Female has entirely rufous forehead, often paler orbital skin. Juvenile is greener, less rufous-tinged, above, has variably strong element of grey or green below. Race *reichenowi* generally paler, has blackish bare orbital skin, often black-tipped feathers on lores, more rufous above; race *kinneari* has darker plumage. **Voice.** Short sharp "chi" or "tsick"; fast high-pitched trill starting with call, "chi-rrrrrrrr" or "ti-i-i-i-i", by territorial male, both perched and in flight; series of weak squeaks during close contact in courtship; loud, rapid tinny drumming, often on bamboo, also loud tapping.

**Habitat.** Dense low vegetation in broadleaved evergreen and mixed deciduous forest, also dense second growth and mixed scrub; strong preference for bamboo; often near water. To 1850 m in SE Asia; 250-2130 m in N Indian Subcontinent, and recorded to 2600 m.

**Food and Feeding.** Ants and their brood, small bark beetles (Scolytidae), spiders. Occurs singly, in pairs or in small groups of 4 or 5; joins mixed-species flocks. Forages at low levels, moving rapidly through dense vegetation near ground; climbs bamboo, shrub stems and vines; also forages at times on the ground, hopping among leaf litter. Feeding techniques include frequent pecking; not known to excavate for wood-dwelling larvae.

**Breeding.** Mar-Jun in Indian Subcontinent, Apr-Jul in SE Asia. Courting male hops around crouched female, repeatedly flying above her and dropping down again, with squeaking calls. Nest excavated at low level, c. 50 cm, just below a node in dead bamboo, or in small branch or tree stem; entrance hole 1.3-2.5 cm across. Clutch 2-4 eggs; no data on incubation and fledging periods.

#### Movements.

**Status and Conservation.** Not globally threatened. Fairly common to common in SE Asia, but rare in Malay Peninsula and rare in China; uncommon in Nepal, generally uncommon in India but locally fairly common in E Himalayas, and frequent in Bhutan; local and uncommon in NE & S Bangladesh. Occurs in Kaziranga and Namdapha National Parks (India), Chitwan National Park

(Nepal), Doi Inthanon, Nam Nao and Kaeng Krachan National Parks (Thailand), and Nam Bai Cat Tien National Park (Vietnam). As with other piculets, its unobtrusive behaviour makes it likely to be overlooked. Is able to exploit regrowth and disturbed forest, and does not appear to be under any threat at present.

**Bibliography.** Ali & Ripley (1983), Ali *et al.* (1996), Baker (1919), Bangs & Van Tine (1931), Biswas (1961a), Deignan (1945), Delacour (1951a), Delacour & Jabouille (1940), Duckworth *et al.* (1999), Eames & Robson (1992), Échécopar & Hùe (1978), Evans & Timmins (1998), Grimmer *et al.* (1998, 2000), Harvey (1990), Inskipp & Inskipp (1991), Inskipp *et al.* (1999), Lekagul & Round (1991), Ludlow (1937, 1944), MacKinnon & Philipps (2000), Ripley (1982), Robson (2000), Shankar Raman (2001), Shrestha (2000), Smythies (1986), Stepanyan (1995), Wells (1985, 1999), Zhao Zhengjie (1995).

## Tribe NESOCTITINI

### Genus *NESOCTITES* Hargitt, 1890

## 33. Antillean Piculet

### *Nesocittes micromegas*

**French:** Picumne des Antilles

**German:** Hüpfspecht

**Spanish:** Carpinterito Antillano

**Taxonomy.** *Picumnus micromegas* Sundevall, 1866, Brazil; error = Hispaniola.

No obvious close relatives. Two subspecies recognized.

#### Subspecies and Distribution.

*N. m. micromegas* (Sundevall, 1866) - Hispaniola.

*N. m. abbotti* Wetmore, 1928 - Gonâve I, off W Hispaniola.

**Descriptive notes.** 14-16 cm; 26-33 g. Unmistakable; the largest piculet, roughly twice the size of any other. Male has yellowish-green forehead, crown sides and hindneck, lemon-yellow crown to nape with patch of orange-red to dull red in centre of hindcrown, sometimes a few white spots on nape; buff-white lores and nasal tufts; dull whitish ear-coverts barred olive, more uniform olive-grey neck sides with variable white spots; white moustachial region spotted or barred greyish-olive; dull olive-green to yellow-green upperparts faintly tinged rusty-bronze, wing-coverts and tertials edged and tipped brighter

paler greenish; brown primaries and secondaries edged yellow-green; uppertail brownish-olive, suffused bronze; white chin and throat faintly tinged yellow, with few small dark spots or bars; rest of underparts pale yellowish-white, breast sometimes deeper yellow, all with variably broad dark streaks; underwing greyish-olive; bill short, culmen curved, and narrow and flattened between nostrils, blackish; iris brown to red-brown or red, orbital skin dark grey; legs dark green-grey. Female is larger than male, lacks red on hindcrown. Juvenile duller, both sexes with crown pattern as adult female but yellow colour less bright, belly obscurely barred rather than streaked; may become bare-crowned for short period, but soon acquires adult feathers. Race *abbotti* is paler, with greyer upperparts, sometimes white spots extending to mantle side, plainer white throat, less heavy streaks below, both sexes with less yellow on crown. **Voice.** Single mechanical "pit" and "pew" notes in alarm; loud, rapid, musical whistling "kuk-ki-ki-ke-ku-kuk", sometimes associated with alarm call, as long-distance signal between pair-members, also in territorial encounters; short series of weak "wiii" notes in close proximity to conspecific; continuous noisy "yeh-yeh-yeh-yeh" chatter during fights; not known to drum.

**Habitat.** Humid to dry primary and secondary forest, also mixed pine (*Pinus*) and broadleaved forest, and especially mixed desert scrub and thorn-forest in semi-arid regions; also mangroves and, locally or more rarely, orchards and dense cultivation and plantations. Favours dense undergrowth. Both in lowlands and in mountains, occurring up to 1800 m in Sierra de Bahoruco; in pine-forest zone prefers elevations below 300 m.

**Food and Feeding.** Mainly insects, especially ants and small beetles; also other arthropods; also eats relatively large amounts of fruit. Occurs singly or in pairs, partners keeping loose contact. Forages mainly in understorey below 8 m, flitting rapidly through vegetation; often perches and moves in passerine-like manner, zigzagging through entangled vegetation; also moves up to the crown, from where it departs in fast direct flight to another feeding site, which may be some distance away. Forages on vines, small branches and twigs, stalks of herbaceous plants, and leaf clusters, much less commonly on trunks. Feeds mainly by gleaning; also makes occasional weak pecks, often directed laterally; also probes in fruits and flowers, and in leaf or pine-needle clusters.

**Breeding.** Mar-Jul. Nest excavated at below 5 m in stub, small tree, palm or fence post. Territorial; aggressive calling bouts and jerky head-swinging displays directed at rivals. Clutch 2-4 eggs; incubation and fledging periods not documented.

#### Movements.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Hispaniola EBA. Common in most of range, but less numerous in W (Haiti); has been reported as fairly common on Gonâve I, although destruction of habitat has been a serious problem on this island. Habitat destruction generally considered a potential threat, particularly in Haiti; much forest has been lost since 1970's. Hunting possibly also a problem. Occurs in several protected areas, e.g. Sierra de Bahoruco and Este National Parks (Dominican Republic). Environmental matters are generally given scant attention in the region, especially by decision-makers, and programmes are required aimed at encouraging local human populations to safeguard their natural resources. Lack of adequate laws to protect wildlife, and to safeguard habitats, could become a major problem unless addressed as a matter of urgency.

## Subfamily PICINAE

### Tribe MELANERPINI

## Genus *MELANERPES* Swainson, 1832

### 34. White Woodpecker

#### *Melanerpes candidus*

**French:** Pic dominicain

**German:** Weißspecht

**Spanish:** Carpintero Blanco

**Taxonomy.** *Picus candidus* Otto, 1796, Cayenne.

Distinctive; sometimes placed in monotypic genus *Leuconerpes*, but shows many morphological similarities to typical *Melanerpes*. Monotypic.

**Distribution.** Lower Amazon (W to R Madeira), and from extreme SE Peru (Pampas del Heath), S Mato Grosso and NE Brazil (N Maranhão) S to E Bolivia, N Argentina (S to Córdoba, N Buenos Aires) and W & S Uruguay.

**Descriptive notes.** 24-29 cm; 98-136 g. Smallish to medium-sized, very distinctive woodpecker. Male has almost entire head and underparts white to creamy-white, occasionally slightly buff-tinged (and often becoming stained brownish); dusky to blackish loreal line, narrow black stripe from lower rear of eye curving down to mantle; pale lemon-yellow lower hindneck; black mantle to upper back, wing-coverts and tertials, slightly glossed blue, white lower back to uppertail-coverts; flight-feathers brownish-black; uppertail brownish-black, some white at base, usually a few white spots in distal part of outer feathers; yellow patch in

centre of lower belly of variable extent (occasionally reaching lower breast); underwing grey-brown, coverts black; longish bill slightly chisel-tipped, culmen curved, moderately broad across nostrils, black, paler (even greenish or whitish) at base; iris white to pale bluish-white or yellow, very broad orbital ring golden-yellow; legs olive to grey-green or brownish. Female lacks yellow on hindneck. Juvenile has dark areas browner, less glossy, white areas more buff-tinged, yellow on belly duller, iris grey, orbital ring possibly bluish; young male with yellow extending from hindneck or nape up to crown, female with broken band of yellow in nape area. **Voice.** Common call when perched "ghirreh" or "kreer"; very distinctive "krr-krr-krr" or "cree-cree-cree-creek" in flight, recalling a tern (*Sterna*).

**Habitat.** Principally dry subtropical forest, woodland and open wooded areas, savannas with scattered trees, and dry scrub areas; often at forest edge and in cultivated areas, where it inhabits palm groves and orchards. Not uncommonly seen in stands of *Eucalyptus*, and recorded in other exotic trees (*Salix*, *Populus*) in Argentina. Mainly lowlands, locally to c. 2200 m.

**Food and Feeding.** Predominantly fruits, also seeds and honey; in addition, insects, including wild bees and wasps and their larvae. Also recorded feeding on meat hung up to dry. Usually observed in small groups of c. 5-8; sometimes accompanies *Colaptes* species. Often visits more open places; may fly long distances across open country in relatively straight (non-undulating) flight, pausing to forage on any trees encountered. Arboreal, foraging mostly by pecking and gleaning. Opens nests of hymenopterans to take their brood and honey. Occasionally catches insects on the wing.

**Breeding.** Season Sept-Nov. Possibly social breeder, but details insufficiently known. Nest not described; apparently able to use holes among rocks. Display flights occur during breeding season. Clutch 3-4 eggs; incubation by both parents, period unrecorded; fledging period 36 days in captivity.

**Movements.** Apparently resident. Recent records in coastal Rio Grande do Sul possibly only of wandering individuals, but might represent expansion of breeding range.

**Status and Conservation.** Not globally threatened. No data on numbers and density; probably not uncommon. Rare in Peru. Occurs in several protected areas, such as Serra da Canastra and Das Emas National Parks and Sooretama Biological Reserve (Brazil). Appears to have expanded its range in S since early 1990's. Causes some damage locally in commercial fruit plantations, e.g. of oranges, and is sometimes persecuted as a result. Trapped for cage-bird trade in and around Buenos Aires (Argentina).

**Bibliography.** Aleixo & Galetti (1997), dos Anjos & Schuchmann (1997), Belton (1984), Bodrati (2001), Brace *et al.* (1997), Brooks *et al.* (1993), de Bustamante (1997), Buzzetti (2000), Canevari *et al.* (1991), Capper *et al.* (2000), Chebez *et al.* (1999), Clements & Shany (2001), Contreras (1983), Contreras *et al.* (1990), Davis (1993), Dubs (1992), Figueiredo & Lo (2000), Figueiredo *et al.* (2000), Fjeldså & Krabbe (1990), Graham *et al.* (1980), Lando & Haene (1996), López (1997), Macklin (1937), Mauricio & Dias (2000), Melo-Júnior (2001a), Navas & Bó (1993), Parker & Goerck (1997), de la Peña (1994), Pereyra (1950), do Rosário (1996), Scott & Brooke (1985), Short (1975, 1985b), Sick (1993), da Silva *et al.* (1997), Stotz *et al.* (1996), Stradi & Hudon (1998), Stradi *et al.* (1998), Tobias *et al.* (1993), Wetmore (1926).

### 35. Lewis's Woodpecker

#### *Melanerpes lewis*

**French:** Pic de Lewis

**German:** Blutgesichtsspecht

**Spanish:** Carpintero de Lewis

**Taxonomy.** *Picus Lewis* G. R. Gray, 1849, no locality = Montana, USA.

Rather distinctive; sometimes placed in monotypic genus *Asyndesmus*, but shows many similarities to typical *Melanerpes*. Monotypic.

**Distribution.** Coastal ranges and foothills of Rocky Mts from S British Columbia S to Arizona and New Mexico, E to South Dakota, Wyoming and SE Colorado; in winter mostly in S parts of range.

**Descriptive notes.** c. 26-29 cm; 85-138 g. Small to medium-sized woodpecker, unmistakable; flies with slow beats in straight line, not undulating, appears very dark. Both sexes have green-glossed black head, deep crimson-red feathers with black bases on lower forehead, lores, around eye and on cheeks, brownish-black chin and throat; black-based silver-grey feathers on rear neck sides usually forming collar around hindneck, also continuing broadly across breast; blackish upperparts, including wings and uppertail, strongly glossed green, normally more blue-green on flight-feathers; secondaries occasionally with small

white tips, rarely outer tail narrowly edged white; belly silver-pink, becoming greenish-black on lower flanks and undertail-coverts; underwing and undertail blackish-brown; longish bill almost pointed, culmen slightly curved, fairly broad across nostrils, slaty-grey to blackish; iris dark red-dish-brown; legs bluish to blue-black. Juvenile is drabber, less glossy than adult, has browner head and neck, no or minimal red on face, no silvery collar, dull red belly variably barred whitish and brown, eyes brown; has prolonged moult, sometimes not fully until autumn or early winter. **Voice.** Series of short, rather loud and harsh "churr" calls, usually 3-8 in quick succession, by male during breeding season, each call about half as long as equivalent call of *M. erythrocephalus*; throughout year, "Chatter-calls" comprising rapidly descending series of short squeaks, most frequently in encounters of any kind; in alarm, single "yick" notes by male, double "yick-ick" by female. Drumming infrequent, restricted to courtship period, a weak roll followed by 3 or 4 taps.

**Habitat.** Breeds in open habitats with some dead trees with decayed wood for nesting, and with rich food sources: primarily open pine forest, especially of ponderosa pine (*Pinus ponderosa*), but logged or burned forest as well as open riparian woodland with cottonwoods (*Populus*) also important; occasionally oak (*Quercus*) woodland, orchards, even farmland with suitable trees. In areas of contact with *M. erythrocephalus*, more on cultivated land and at edges, whereas latter prefers riverine woodland and clearings. In winter, most commonly oak woodland and commercial orchards (e.g. almond, walnut, pecan); areas with good supply of corn also favoured. From sea-level to 2000 m, to 2800 m in Arizona.

**Food and Feeding.** In spring and summer, various insects, especially ants and other Hymenoptera, also beetles, Orthoptera (mainly Tettigoniidae); also fruits (e.g. cherries) and berries. In winter, mostly acorns and nuts obtained from stores laid up in autumn; if latter type of crop in ample supply, as in almond plantations or exceptionally in corn silos, may do without stores. Probably the most specialized of all woodpeckers in flycatching; spends much time scanning surroundings from prominent perch; approaches prey in crow-like flight, with elaborate manoeuvres leading to final capture; glides back to perch. Over 10% of flycatching performed in continuous flights lasting several minutes, when several insects may be taken. Also takes insects on ground or in low brush, showing considerable agility when moving among outer branches. Also gleans, probes, taps lightly, chips off small pieces of bark; most frequently searches visually for prey. In autumn, harvests acorns and nuts, shells nuts in several anvils; stores food in natural crevices, occasionally after widening cracks; tends stores by moving individual items around, to inhibit fungal growth. When superabundant, insects, such as swarming carpenter ants (*Camponotus*), are also stored in cracks near nest, and later fed to young. Individual food caches defended vigorously; competition for stored mast is intense, main competitor *M. formicivorus*.

**Breeding.** Apr-Sept, mostly May-Jul; breeds 1-3 weeks later in S of range or at low altitudes than in N or uplands. Apparently monogamous, with lifelong pair-bond. Nest 1.5-5.2 m up in cottonwood, conifer, oak or other tree, most (c. 75%) in dead stub, or occasionally in electricity pole; entrance diameter 5-7.5 cm, cavity depth 22-8-76-2 cm; may use same nest in consecutive years, or male selects winter roost as nest-site; only infrequently excavates new nest-hole, and then prefers to adapt natural hollow or flicker (*Colaptes*) hole; male defends immediate nest vicinity from intruders. Displaying male exposes pink feathers of flanks and belly; perches on horizontal limb, wings extended, head lowered, silvery feathers of throat and upper breast fluffed; also glides around nest tree with wings held at high angle, alighting at nest entrance. Clutch 4-9 eggs, usually 6-7, increasing from S to N; incubation period c. 14 days, nestling period 4-5 weeks; parents seem to contribute equally to feeding and brooding, but male alone spends the night in nest and possibly removes faecal sacs more often; fledged young remain near nest with adults for at least 10 days, sometimes each parent accompanies part of the brood; post-breeding flocks in autumn or early winter, within which relationship between adults and their offspring is not certain. Success variable: in Colorado, 60-2% of nests in agricultural plains with cottonwood produced at least 1 fledgling, but only 29-4% in cottonwood-oak woodland in foothills; in Idaho, success greater in burned pine forest than in cottonwood forest. First breeds probably at 1 year.

**Movements.** Mostly migratory. Because of marked seasonal changes in diet, has to move variable distances to non-breeding grounds that provide acorns or nuts; populations of Idaho, Wyoming and Montana migrate longer distances, c. 50% of population in SE Colorado may be resident throughout year. Migrants generally winter within S part of breeding range (S from SW Oregon, C Utah and C Colorado), also locally S to NW Baja California, W & C Arizona and S New Mexico, more rarely to N Mexico (S to Sonora and Chihuahua); non-breeding distribution heavily dependent on weather conditions and distribution of acorn crops. Migration sometimes spectacular, with more than 2000 birds in small groups and loose flocks passing a single point in 1 hour; before arrival at wintering grounds, nomadic flocks may exploit habitats in mountains or visit orchards. Arrives on winter grounds in late Sept and first half Oct, staying until late Apr; sometimes in large flocks in winter. Spring return less nomadic than autumn migration, and therefore takes less time.

**Status and Conservation.** Not globally threatened. Locally common to uncommon or rare. No figures for total population size; estimated 700-1200 breeding birds in British Columbia in 1990. Maximum density in Pacific Northwest (Blue Mts) c. 16 pairs/ha, but probably wide annual and local variation dependent on food supply. Global population thought possibly to have decreased by c. 60% since 1960's; reduction in breeding range recorded in British Columbia, NW Washington, Oregon, California. Habitat degradation and loss, especially of open ponderosa pine forest and cottonwoods, considered major factors in decline, at least locally, and loss of oakwoods in wintering range may also be important; nest-site competition not thought to be an important problem for

### 36. Guadeloupe Woodpecker

#### *Melanerpes herminieri*

**French:** Pic de la Guadeloupe **German:** Guadeloupespecht **Spanish:** Carpintero de la Guadalupe

**Taxonomy.** *Picus Herminieri* Lesson, 1830, North America; error = Guadeloupe.

Sometimes placed in a monotypic genus *Linneopicus*, but shows many similarities to typical *Melanerpes*. Monotypic.

**Distribution.** Guadeloupe (Lesser Antilles).

**Descriptive notes.** c. 24 cm; male 86-97 g, female 69-78 g. Rather small, distinctive woodpecker, appearing all black in the field. Male has head and upperparts, including wings and tail, black with blue gloss; tail feathers and inner parts of flight-feathers more brownish-black, unglossed; sooty-black underparts, dull red tips of feathers from throat to belly, blackish-brown flanks and undertail-coverts; long bill somewhat pointed, culmen slightly curved, narrow across nostrils, blackish; iris deep brown; legs blue-black. Female as male, but slightly smaller, bill up to 20% shorter. Juvenile is duller, less glossy.

browner, underparts suffused dull orange-red. **VOICE.** Main call a single or repeated "kwa", female higher-pitched; series of variable "wa-wa-wa" or "kakakakaka" calls when excited, in various contexts; loud "ch-arrrh", also in series of 3-8 notes, apparently to maintain contact; "tratratrata" by adult arriving for change-over at nest. Drums in relatively slow rolls, mean duration 1-3 seconds at 11 strikes per second, may contain an initial beat or beats out of rhythm; short, weak series in mutual tapping at or in cavity.

**Habitat.** Occurs in all available forest types within range. Prefers humid semi-deciduous forest and evergreen forest, but also uses swamp-forest and mangroves; occurs also near plantations with larger trees. Present from sea-level up to c. 1000 m; most common on wooded hills at elevations of 100-700 m.

**Food and Feeding.** Diet includes termites (Isoptera), ants, insect larvae, myriapods and other arthropods; also many seeds and fruits when available, especially those of *Clusia*; in one study, 16 species of fruit recorded eaten. Reported also to take ripening cacao pods. Female observed eating shell of white crab (*Cardisoma guanhumi*). Nestling diet better known: one study found orthopterans most common (44% of items), followed by larvae of beetles and Diptera (20%), the tree-frog *Eleutherodactylus martinicensis* (11%), adult beetles (Curculionidae, Cerambycidae, Scarabaeidae), caterpillars, Gastropoda, beetle and dipteran pupae, millipedes (Diplopoda); also unidentified spider: chicks also fed fruits and seeds. Forages mostly in canopy, male more often on trunks and larger branches, female more on smaller branches; visits treetops to obtain fruits. Does not remain long at one spot when foraging, but regularly revisits clusters of fruits and fruit-bearing trees. Main techniques are pecking, probing and gleaning; clings upside-down when obtaining fruits, or perches on or beside larger ones. Bigger prey such as tree-frogs, cockroaches (Blattodea) or large orthopterans usually placed in anvil for treatment; crab shell also recorded being treated in anvil. Smaller fruits swallowed whole; larger ones may be carried to tree and secured in crack or under bark, before flesh removed.

**Breeding.** Jan-Aug, mostly from Apr. Monogamous; solitary. Nest 2-20 m up in dead coconut palm (*Cocos nucifera*), rarely in live one, occasionally in other tree or in utility pole, excavation completed in c. 10 days; mean dimensions of entrance hole 6.2 cm high and 5.7 cm across, with tunnel 4.6 cm, cavity depth 31.9 cm, cavity diameter 12.1 cm; sometimes reused in successive years; territorial. Clutch up to 5 eggs, laid at daily intervals, but no more than 3 young reared; incubation by both parents, period 14-16 days; both also feed chicks, c. 1 food delivery every 12-15 minutes; nestling period 33-37 days; fledglings, which often still retain egg-tooth, stay with parents for several months, sometimes until next breeding season. Success generally low: at 22 nests, 100 eggs produced 10 fledglings. First breeds probably at 1 year.

**Movements.** Resident; juveniles disperse short distances. Recorded once on Antigua, c. 80 km N of Guadeloupe, but probably blown there by hurricane or tropical storm.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in Lesser Antilles EBA. Estimated population 10,330 pairs, of which 7920 on W half of island (Basse-Terre) and 2410 on E half (Grande-Terre). On Basse-Terre, average territory size in semi-deciduous forest on igneous soil 2 ha in N and 5 ha in S, in evergreen forest 2.3 ha; on Grande-Terre, average territory size in semi-deciduous forest on clay soil 2.5 ha in N and 11 ha in S, in swamp-forest 3.3 ha and in mangrove-forest 3.0 ha. Has adapted to all forest types, which should make it less vulnerable. A major adverse factor is hurricanes, which can have a serious impact through destroying habitat and, particularly, nesting sites. In addition, road-building and other human activities have already led to loss of much habitat on the island. Although the species is not at present endangered, continuing deforestation, especially on Grande-Terre, could become a significant threat; even within the National Park of Guadeloupe, on Basse-Terre, felling is permitted for the tourism industry. Main conservation priority is effective protection of all non-fragmented forest areas with dead trees and palms for nesting. Assessment of possible effects of biocides on the local environment and on the species' ecology is also required. Potential threat posed by introduced rats (*Rattus*) also needs investigation. Although this woodpecker has long been protected on the island, it is considered a bad omen by hunting parties and is still sometimes shot.

**Bibliography.** Anon. (1998b), Benito-Espinal & Hautcastel (1988), Bond (1985), Cruz (1974a), Faaborg (1985), Feldmann & Villard (1993), Feldmann *et al.* (1998), Raffaele *et al.* (1998), Short (1974d, 1985b), Stattersfield & Capper (2000), Stotz *et al.* (1996), Villard (1995, 1997, 1999a, 1999b, 2000, 2001), Villard & Pavis (1998), Villard & Peacock (1999), Villard & Pradel (1998), Villard & Rousteau (1998).

### 37. Puerto Rican Woodpecker

#### *Melanerpes portoricensis*

**French:** Pic de Porto Rico **German:** Scharlachbrustspecht **Spanish:** Carpintero Puertorriqueño

**Taxonomy.** *Picus portoricensis* Daudin, 1803, Puerto Rico.

Monotypic.

**Distribution.** Puerto Rico and nearby Vieques I (Greater Antilles).

**Descriptive notes.** c. 22 cm; 45-72 g. Small, distinctive woodpecker. Male has white forehead, lores and narrow circle of feathers around eye, tinged buffish on forehead; blue-glossed black crown to hindneck, ear-coverts and narrow line beneath eye, bright red moustachial region, chin and throat; most of upperparts, including wing-coverts, glossy blue-black, lower back to uppertail-coverts white; brownish-black flight-feathers slightly glossed blue on edges, with variable amount of white at bases of inner webs of tertials, secondaries sometimes narrowly tipped white; uppertail glossy blue-black, outer feathers occasionally tipped white; bright red breast with blue-black of neck extending onto breast side (occasionally black-based feathers across entire breast), red continuing down central belly, pale buffish-brown sides and flanks, pale brownish undertail-coverts; underwing brown, coverts black and white; longish bill slightly chisel-tipped, culmen curved, fairly broad across nostrils, blackish; iris dark brown; legs greyish. Female is smaller and c. 16% shorter-billed than male, has chin, throat and often moustachial region largely brown, red of belly usually narrower and sometimes orange-yellow; plumage occasionally much as male. Juvenile less glossy, and with red below less extensive and more orange-tinged, male usually with a few red feather tips on crown. **VOICE.** Wide variety of calls, most commonly "wek, wek, wek-wek-wek-wek-wek" or similar, increasing in volume and speed; also harsh sounds, e.g. rolling "gurr-gurr"; also "kuk" notes like those of domestic hen, and "mew" notes. Drums weakly and infrequently.

**Habitat.** Wooded areas, ranging from mangrove-swamps and coconut plantations on coast to montane forest; also shaded coffee plantations, less frequently in secondary forest. Appears to be most numerous in hills and lower mountains.

**Food and Feeding.** Animal food principally wood-boring beetle larvae, ants and earwigs (Dermaptera), also grasshoppers, bugs, occasionally frogs and lizards. Vegetable matter constitutes about one-third of diet, comprises seeds and fruits from various palms, trees (*Ficus*) and shrubs, and possibly bark. Forages singly, in pairs or in small family groups of up to 5 birds; sometimes loose groups of up to 10 individuals in non-breeding season. Forages mainly on trunks and branches. Sexes differ in foraging strata and techniques: male tends to forage in lower and middle parts of trees and uses more pecking and probing, female more frequently in middle layers and in canopy and prefers gleaning. Sexual differences most pronounced in harsh conditions of the dry season: respective percentages of gleaning and pecking/hammering 54% and 31% for females, compared with 27% and 45% for males.

**Breeding.** Nest-building from Jan, laying mostly in Apr-May. Solitary; possibly occasionally colonial. Nest excavated in dead stump, usually high in tree, especially coconut (*Cocos nucifera*), sometimes in pole; territory defended. Clutch up to 4 eggs; incubation and fledging periods not documented; at one nest watched for 5-25 hours, total of 20 food deliveries to chicks shared equally by male and female, 1 delivery every 16 minutes; both parents continue to feed young for 2 weeks after fledging, and family-members stay together for longer period. Nesting success variable, 77% in 1999 but as low as 8% in 1998.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Puerto Rico and the Virgin Islands EBA. Common and widespread on Puerto Rico; rare on Vieques. No data on population size. Not surprisingly, found to be much more common in areas with good availability of nesting and foraging sites (e.g. coffee plantations) than in other areas (e.g. second growth). Huge annual variation in breeding success possibly due partly to ectoparasite infestation; *Philornis* parasite found on 11 of 23 individuals in 1998, but on none in 1999. No data on any other potential threats; hurricanes probably pose the most serious danger.

**Bibliography.** Anon. (1998b), Biaggi (1983), Bond (1985), Bowditch (1904), Cruz (1974a), Faaborg (1985), Leck (1972), Muiznieks & Collazo (1999), Raffaele (1989), Raffaele *et al.* (1998), Short (1985b), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Villard (1999a, 2001), Wallace (1969, 1974a, 1974b).

### 38. Red-headed Woodpecker

#### *Melanerpes erythrocephalus*

**French:** Pic à tête rouge **German:** Rotkopfspecht **Spanish:** Carpintero Cabecirrojo

**Taxonomy.** *Picus erythrocephalus* Linnaeus, 1758, America = South Carolina.

Possibly closer to *M. portoricensis* and *M. herminieri* than to *M. formicivorus*. Slightly longer-winged (more migratory) populations of W Great Plains S & W to C Colorado sometimes separated as race *caurinus*, supposedly also with slightly deeper yellow wash below; tone of underparts, however, varies greatly among all populations, and subspecific division considered unwarranted. Monotypic.

**Distribution.** Breeds in extreme S Canada from S Manitoba (L. Winnipeg) E to New Brunswick, and in C & E USA from Montana (E of Rocky Mts) across to Atlantic coast, S to C Colorado, C New Mexico, Gulf of Mexico and Florida.

**Descriptive notes.** c. 24 cm; 56-97 g. Rather small woodpecker with distinctive plumage pattern. Both sexes have head, neck and throat to upper breast red, rarely some admixed orange or yellow feathers; glossy blue-black mantle, upper back and wing-coverts, white lower back to uppertail-coverts often with indistinct black shaft streaks; brown primaries and outer secondaries, white inner secondaries and tertials with indistinct black shaft streaks and occasionally hint of barring; uppertail blackish-brown with faint blue gloss, outer feathers narrowly tipped white, outermost edged white; black line across upper breast; rest of underparts white, with dull yellowish to reddish wash of variable intensity and extent; white or creamy undertail-coverts, often with indistinct shaft streaks; underwing as above, but coverts black and white; long bill chisel-tipped, culmen slightly curved, broad across nostrils and at base, bluish-grey, paler towards base; iris brown; legs olive-grey. Female slightly smaller than male. Juvenile has similar pattern, but colours brown and white, usually some dull red on nape or around eye, mantle to back barred, white secondaries partly barred, throat

streaked, upper breast barred, rest of underparts variably streaked; acquires adult plumage in gradual moult through autumn and winter, most with much red on head, blue-black back and largely unstreaked below by Dec (some already fully adult by late Sept/Oct), but barring on secondaries may still be evident in May. VOICE. Many, variable calls: aggressive "quirr" in fast series of 5-7 notes, given throughout year, most frequently prior to intraspecific encounters or copulation; in breeding season very rapid series of "churr" or "kweer", or with higher-pitched initial note, "kwi-urr", probably as announcement and as contact between pair-members, sometimes by 2 birds simultaneously; also quieter variants in close encounters, become chattering "er-er" or "er-r-r" during copulation; "chee-chee" from nestlings. Drumrolls in breeding season weak and short, c. 20-25 strokes per second; mutual tapping, with 1 bird inside hole and the other at entrance, is typical.

**Habitat.** Mature lowland forest with dead trees for nesting, open areas for flycatching, and relatively open understorey allowing access to ground; open deciduous woodland, especially with beech (*Fagus*) or oak (*Quercus*); also riparian forest, pine (*Pinus*) forest, various types of wooded savanna, orchards and agricultural land, including in villages and suburbs; attracted to wooded swamps. In E prefers old woodlots with some undergrowth as in e.g. suburbs and agricultural areas, while farther S favours clearings with some tall stumps; in SE USA, pine scrub, mixed pine and hardwood forest, urban environments, pine-oak savanna, also nests in longleaf pine (*Pinus palustris*) forest. Preference for tall mature forest pronounced in post-breeding season. Also forages in open country, e.g. upland meadows and short-grass areas, such as pastures or golf courses, with scattered deciduous trees or groves; visits burned areas and clearings. Usually in habitats that are less dense and with less undergrowth than those frequented by *M. carolinus*; where occurring with *M. lewis*, is found more in riverine woodland and in clearings, whereas latter tends to prefer agricultural areas and edges.

**Food and Feeding.** About two-thirds of diet is made up of animal matter in spring; seeds and other plant material predominant food in winter. One of the most omnivorous picids: very wide range of prey, including earthworms, lizards, mice, nestlings of hole-nesting and open-nesting birds, eggs, grasshoppers, crickets, beetles and their larvae, caterpillars, adult Lepidoptera, wasps, honeybees (*Apis mellifera*), other arthropods; great variety of fruits, both wild and cultivated, e.g. mulberries (*Morus*), cherries, grapes, apples; also bark, and takes tree sap; in winter, mostly acorns, various types of nut, corn. Generally, flying insects more important than wood-boring larvae, which scarcely figure in diet. Forages singly or in pairs. Visits both live and dead trees, preferring higher levels (12-18 m) and medium-sized limbs (5-30 cm in diameter), may cling to smaller twigs in manner of tit (Paridae); regularly descends to ground; hops on ground and on horizontal branches. Often makes aerial sorties from perch for flying insects. In breeding season, main foraging techniques are hawking insects and gleaning, with some occasional pecks during arboreal foraging; pecking more important during winter. Obtains young of hole-nesting birds by widening hole entrance. Larger animal prey are pounced on and worked with blows of the bill. Places larger insects in crevices or cavities as interim stores. During years with good mast crops, spends most of active time in early autumn harvesting acorns, beechmast, corn and nuts; stores these in pre-existing cracks and bark crevices, breaks items into pieces if too big to fit; sometimes seals stores with wood chips. Defends stores against all intruders, including other woodpeckers; from Sept onwards establishes winter territory, size 0.4-2.0 ha. Dominant over other members of bark-foraging guild, including *M. carolinus*, generally causing them to shift habitat or foraging stratum.

**Breeding.** Apr-Sept, mainly May-Jun; from Feb in S; up to 50% of pairs raise 2 broods. Monogamous, solitary; occasional trios of male and 2 females reported, but possible polygyny unconfirmed. Nest-hole excavated mostly by male, work takes c. 2 weeks (but up to 50 days recorded); at variable height (2-25 m, in Arkansas mainly 7-12.5 m) in dead tree or dead part of tree, typically in barkless trunk, stump or branch, occasionally in live trunk; sometimes uses natural hole, or hole in building or other artificial structure (e.g. pump, pole), occasionally nestbox; territory size in Florida 3.1-8.5 ha. Courtship displays include horizontal posture with head and neck forward, plumage sleeked, also mutual "hide and seek" and chasing. Clutch usually 4-7 eggs, rarely 3-10; incubation by both parents, only male at night, period 12-14 days; both also tend nestlings, female providing c. 75% of feeds after day 12; fledging period 24-27 days, sometimes up to 31 days; young fed by parents for c. 25 days after leaving nest, then chased away. Success in rearing at least 1 fledgling c. 78%; snakes a major nest predator. First breeds at 1 year. Recorded longevity at least 9 years 11 months.

**Movements.** N populations migrate S more or less regularly; NW populations particularly migratory. Non-breeding distribution greatly dependent on abundance of mast; in most years, N limits from S & E Minnesota and SC Wisconsin across to extreme S Ontario, and W limits E Kansas and Oklahoma. Also somewhat nomadic in winter throughout range. Autumn dispersal and migration from Aug to Nov, singly and in small groups; return from winter quarters from late Feb, mostly in Mar, often large numbers along shores of Great Lakes. Migration mostly diurnal. Records outside range not infrequent, especially in W USA, more rarely in W Canada; single vagrant recorded in Bermuda.

**Status and Conservation.** Not globally threatened. Fairly common. Breeding numbers fluctuate, probably greatest in seasons following high productivity of mast. Recorded breeding densities of pairs/40 ha 2-3 in SE USA, up to 6-7 in Oklahoma. Was very common in 19th century, but thereafter decreased; possible causes were loss of some prey species (Orthoptera), also habitat loss; expansion of introduced Common Starling (*Sturnus vulgaris*), a probable nest competitor, may also have been relevant, although studies suggest that present species usually wins such encounters. Destruction of American chestnut (*Castanea dentata*) and American elm (*Ulmus americana*) by fungal disease led to population increase in mid-20th century, e.g. in Illinois c. 24-64 pairs/40 ha after death of elms but only 5 pairs before. Currently appears to be declining over most of range, especially in Florida and in Great Lakes Plain; considered fastest-declining hole-nester in Florida; decline of 2-2% annually in E USA since 1966. Habitat degradation resulting from removal of dead trees and branches in urban areas, and clear-cutting and agricultural development in rural areas, largely responsible for reduction in numbers of this woodpecker; collisions with motor vehicles may also be a contributing factor. Formerly considered a serious pest by farmers and was shot in large numbers, e.g. over 100 shot at a single tree in 1 day; was also shot because thought to do considerable damage to utility poles. Current levels of such persecution only minimal.

## 39. Acorn Woodpecker

### *Melanerpes formicivorus*

French: Pic glandivore

German: Eichelspecht

Spanish: Carpintero Bellotero

**Taxonomy.** *Picus formicivorus* Swainson, 1827, Temiscáltepec, Mexico.

Geographical variation clinal, and some races rather poorly defined. Proposed race *martirensis* (N Baja California) considered indistinguishable from *bairdi*. Race *lineatus* doubtfully distinct from *albeolus*. Seven subspecies currently recognized.

**Subspecies and Distribution.**

*M. f. bairdi* Ridgway, 1881 - NW Oregon S to N Baja California.

*M. f. formicivorus* (Swainson, 1827) - Arizona, New Mexico and W Texas S to SE Mexico (W of Chiapas).

*M. f. angustifrons* Baird, 1870 - extreme S Baja California.

*M. f. albeolus* Todd, 1910 - SE Mexico (E Chiapas, probably also Tabasco and Campeche), NE Guatemala and Belize.

*M. f. lineatus* (Dickey & van Rossem, 1927) - Chiapas E to Guatemala and N Nicaragua.

*M. f. striatipictus* Ridgway, 1874 - Nicaragua to W Panama.

*M. f. flavigula* (Malherbe, 1849) - Colombia (W & C Andes and W slope of E Andes).

variable white streaks and spots (usually also a few red feather tips in centre); rest of underparts white, lower breast with variable black streaking, flanks also streaked, undertail-coverts with black streaks or tear-shaped spots; underwing as above but duller, coverts with white streaks; moderately long bill slightly chisel-tipped, culmen curved, broad across nostrils, black; iris white to yellow-white or pinkish-white, orbital skin grey, sometimes brown or blackish; legs grey to greenish-grey. Female has red on head restricted to hindcrown, bill c. 10% shorter than male's. Juvenile browner and less glossy above, central crown orange (may be less extensive on female), tail often with more white barring on outer feathers, more prominent white shaft streaks on central rectrices, buff-tinted underparts with less contrasting markings on upper breast, some barring across flank streaks, heavily streaked undertail-coverts, eyes initially brown, becoming greyish before turning white. Races differ only moderately in plumage, to lesser extent in size: *bairdi* is slightly larger than other races, with long stout bill, moderately yellow throat, breastband well demarcated and little streaked, less streaking below; *angustifrons* is smallest, with relatively long bill, reduced white on forehead, yellow throat, more heavily streaked below and with more white in breastband, female with red extending farther forward on crown; *albeolus* is very like nominate, but throat palest of all races, underparts with reduced streaking; *lineatus* is like previous, but has slightly yellower throat, white primary patch larger and unbarred, breastband fully streaked; *striatipictus* has throat very yellow, white primary patch narrower and often with some black bars; *flavigula* has rump and uppertail-coverts feathers tipped and edged black, throat very yellow, underparts most heavily streaked of all races, male with red confined to nape, female with no red on head, juveniles of both sexes with fully red crown and nape. VOICE. Rather noisy, with nasal whinnying, laughing or rattling calls: most common is "whaaka-whaaka" or "wa-ka", usually repeated, as greeting and during territorial disputes, at full intensity terminated by rasp, "wa-ka, wa-ka, wa-ka, trtrtr"; repeated "karrit-cut" or "rack-up, rack-up" or varied to rolling "r-r-r-rack-up" in bowing displays, also in presence of predator; in general alarm, vibrating "karrit" calls; more intimate "hick a fack a fack" chatters between group-members in close contact; chatters when attacked by other group-member; also "urrrk" notes (not loud) and "garrick" notes in various contexts; also "squee-trtr" by fledgling when fed by adult. Drums with 2-20 evenly spaced taps, mostly in intraspecific territorial encounters.

**Habitat.** Oak (*Quercus*) woodland, and mixed woodland of pine (*Pinus*) and oak; also Douglas fir (*Pseudotsuga*), redwood (*Sequoia sempervirens*) and hardwood stands where some oaks also present. Mostly in interior and at edges of forest, sometimes in adjacent second growth; also visits clearings and pastures with scattered trees. Migrating birds also sometimes in open areas, e.g. open grassland, desert. Occurs primarily in uplands and associated valleys: above 750 m in USA, but down to sea-level in California; at 500-3000 m in Mexico, locally lower on Caribbean slope; from 1200 m up to tree-line in tropical Central America, straying down to 900 m; on both slopes of Andes between 1400 m and 3300 m in Colombia.

**Food and Feeding.** Acorns; also other vegetable matter, including other seeds (e.g. of pine), oak catkins, berries and other fruits, sap, nectar. Drinks sugar water from feeders. Insects also important, especially flying ants and other Hymenoptera, Coleoptera, Lepidoptera, Diptera, eaten throughout year. Readily eats other birds' eggs, and occasionally takes lizards. Acorns (mostly dried, but green ones also taken) make up c. 50-60% of diet of N populations, and are basic energy source in winter; S populations less dependent on acorns. Nestling food mainly insects (hymenopterans, beetles, hemipterans, homopterans, caterpillars, dipterans); older broods also fed acorns and fruits. Forages singly and in groups, mostly in or near canopy, rarely descending to ground. Acorns picked directly from trees, sometimes several together by breaking off twig, occasionally from ground; usually placed in anvil (crack or crevice in horizontal limb) for treatment, before being swallowed piecemeal. Sap especially important in spring and mid-summer (e.g. Feb-Mar and Jul-Aug in California), obtained by drilling holes 3-19 mm deep and 5-15 mm wide into live oaks; holes exploited by all group-members. Expert fly-catcher, frequently sallies from treetop or post, especially towards dusk, catching 1 insect on each flight; this foraging method most important in spring (Apr-May), often involves the whole group. Also probes (including into epiphytes) and gleans for insects;

occasionally descends to ground to feed on ants. Many groups store acorns in autumn, but this varies geographically (rare among S populations). Acorns stored whole or piecemeal in crevices in bark or wood, including man-made wooden structures, or amid epiphytes in tropics, or often in specially made holes covering large areas of a tree (oak, pine or other) and densely spaced (c. 28 mm nearest-neighbour distances); such "granaries" can contain up to 40,000-50,000 holes, excavated over many years; stores are constantly tended. Other nuts and seeds similarly stored when available; some animal prey stored in appropriate places. Food stores and anvils, as well as sap trees and favourite hawking perches, vigorously defended.

**Breeding.** In USA, Mar-Jul and less often also Aug-Nov in C California, mostly May-early Sept in New Mexico, from Jun in Arizona; Apr-Aug in Central America; May-Jun, occasionally to Sept, in Colombia; not all groups breed in any one year; sometimes 2 or even 3 broods in a season, at 2-month intervals. Some populations monogamous, especially in Arizona and in S of range; others co-operative and polygynous, or polygynandrous in groups usually of 1-4 (sometimes up to 7) reproducing related males and 1 breeding female, or with 2 or 3 breeding females (usually sisters of first) in c. 20% of groups, and up to 10 helpers (group's offspring of previous years); joint nesting of females more likely as population size increases. Nest-hole excavated 2.3-21 m up in dead, usually well-decayed tree; if new nest made, all group-members participate in task, which may take up to 3 months; internal diameter c. 15 cm, depth 22-70 cm; hole often reused for many years; mean territory size in California 6 ha, hole defended vigorously, in groups females very aggressive, destroy rivals' eggs but unable to prevent laying in nest by subordinate females. Clutch (including multiple-female layings) 4-6 eggs, average 5.06, clutch size increasing with latitude; incubation by both parents, minimal contribution by any helpers present, period 11-12 days; chicks brooded and fed by all group-members, female helpers contributing greater effort than males, feeding rate variable depending on e.g. group size; fledging period 30-32 days; fledglings fed by parents, or group-members, for several weeks, may then disperse, females earlier than males, and form temporary breeding pairs, or remain in parental territory for at least 1 year; in groups, juveniles in high-quality territories tend to stay on and become helpers, many broodmates stay together for entire life and share mates. Success variable: about two-thirds of eggs hatch, of which two-thirds produce fledglings; in a study in California, groups with stored acorns still available started breeding earlier, had larger clutches and fledged more than 5 times as many young as groups without stores; jointly nesting females raise c. 35% fewer offspring per year than females which nest singly, but lifetime reproductive success about equal since females sharing nest with another have marginally better survival. First breeds at 1 or 2 years, some not until 6 years. Recorded longevity at least 16 years for males, at least 15 years for females.

**Movements.** Mostly resident; occasional wandering, sometimes on large scale, in response to food shortage. Juveniles disperse short distances, females farther than males. In SE Arizona (near Huachuca Mts) and adjacent Mexican mountains apparently wholly migratory in most years; presumed to move S into oak forests of Sierra Madre, in N & W Mexico. Occurs regularly outside normal range; recorded N to British Columbia (Canada) and NE to North Dakota.

**Status and Conservation.** Not globally threatened. Common in most of range; common to fairly common in Mexico and Central America; local in Colombia. Often the most abundant woodpecker within its range in USA. Occurs in many protected areas and relatively undisturbed areas throughout its range. Numbers vary locally according to abundance and fruiting of oaks; thus, populations limited largely by that factor, and also by availability of storage sites. Was formerly killed for its feathers and for food. Since second half of 20th century, however, habitat loss and degradation are far greater threats; conversion of oak and pine-oak forest to agricultural use has led to substantial loss of habitat; species may have declined considerably in SW USA, Mexico and possibly elsewhere as a result of overgrazing of montane, riparian and pine-oak habitats; however, surveys in early 1990's indicate numbers of present species to be on increase. Competition for holes from introduced Common Starlings (*Sturnus vulgaris*) may be a limiting factor. Sometimes shot, both legally and illegally, to prevent damage to nut and fruit crops. Nevertheless, remains very common in most areas and adapts well to human presence, readily utilizing man-made structures for roost-holes and food-storing. Preservation of its preferred woodland habitats, with sufficient old snags and dead branches, should ensure its future.

## 40. Black-cheeked Woodpecker

### *Melanerpes pucherani*

**French:** Pic de Pucheran **German:** Schläfenfleckspecht **Spanish:** Carpintero Centroamericano  
**Other common names:** Pucheran's Woodpecker

**Taxonomy.** *Zebrapicus Pucherani* Malherbe, 1849, Tobago; error = Colombia. Sometimes placed in a separate genus *Tripsurus*, along with *M. chrysosauca*, *M. cruentatus* and *M. flavifrons*. Forms a superspecies with first of those, or both sometimes included in the superspecies represented by last two. N populations sometimes separated as *race perileucis*, with supposed tendency towards stronger white barring on upperparts and wings, but much overlap occurs with S populations and racial separation considered not sustainable. Monotypic.

**Distribution.** S Mexico (Veracruz, Chiapas) S to W Colombia and W Ecuador (S to El Oro; may also occur in W Loja).

**Descriptive notes.** c. 17-19 cm; 42-68 g. Male has golden-yellow forehead, red crown and nape, variable amount of black at side of forecrown (and often some white feathers at front edge); white

line behind and slightly higher than eye, black around eye and through ear-coverts down to neck side and hindneck; whitish lores, cheeks, chin and upper throat; black mantle and upper back barred white, black scapulars unbarred or partly barred, white lower back to uppertail-coverts tinged pale buff, occasionally faintly barred or streaked blackish; wing-coverts black, greater and some medians spotted white; flight-feathers black or brownish-black, narrowly tipped white when fresh, all but outer webs of outer primaries barred white (bars broadest on tertials); uppertail black, central feathers variably barred white, sometimes indication of bars on outer feathers; lower throat and breast olive-buff, tinged grey, feathers initially tipped yellowish; rest of underparts buffish-white, red on centre of belly, with strong arrowhead barring; underwing barred dark and white; undertail yellow-brown; longish bill almost pointed, culmen curved, broad across nostrils, black, usually paler base of lower mandible; iris brown, orbital skin brown to greyish; legs greenish-grey or olive. Female is somewhat smaller than male, has forecrown white to buffy-white, black border extending backwards and then across hindcrown, red confined to nape. Juvenile is duller, browner with more diffuse barring above, has duller barring below, red of belly paler and less extensive, male with orange-red on nape and red on crown, female with far less red (and often barred) on crown. Voice. Commonest call a series of c. 4 short rattling trills on same pitch, "churr, churr, churr, churr" or "cherr", higher-pitched than *M. rubricapillus*, less nasal than *M. aurifrons*; also longer smoother rattle, and loud full-toned "krerr"; also higher-pitched piercing "chirriree" or "keereereek" recalling Boat-billed Flycatcher (*Megarhynchus pitangua*). Drumming infrequent, by both sexes.

**Habitat.** Humid and wet evergreen forest, forest borders, scattered tall trees in clearings, and old secondary growth and abandoned plantations; enters gardens, sometimes far from forest. Replaces *M. rubricapillus* in more wooded areas. Lowlands and foothills, to 700-900 m, occasionally 1200 m; locally to 1500 m in Ecuador.

**Food and Feeding.** Spiders, termites, beetles, grubs, ants, caterpillars, and aerial insects. Also eats large quantities of plant material, including fruits, berries, seeds of large bromeliads (may even be fed to nestlings), arils and catkins of *Cecropia*; drinks nectar from large flowers of balsa and kapok trees. Forages singly or in pairs, occasionally in larger family parties; 12 or more individuals may gather at fruiting trees; joins mixed-species flocks. Forages mostly in upper and middle levels inside forest. Most frequently probes crevices and cracks in bark, bases of epiphytes, also pecks and hammers dead wood. Gleans insects from trunks, branches and lianas, often searches epiphytes for animal prey and seeds; plucks fruits regularly; sallies for aerial insects. Moves actively, and peers; reaches for prey, also clings with great agility on underside of branches and twigs.

**Breeding.** Mar-Jul. Nest-hole 4-30 m up in dead trunk (including of palm) or branch, in one case cavity 35 cm deep, entrance hole 10 x 8 cm; used by male also as roost-hole, at least sometimes joined by female. Clutch 2-4 eggs; incubation by both sexes, period 14 days; in captivity fledging period c. 3 weeks, fledglings may return to nest to roost, adults may start second brood and still tolerate young of previous one, even in relatively small aviary.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common to fairly common throughout range. Occurs in several protected areas, including Tikal National Park (Guatemala), Braulio Carrillo and Cahuita National Parks and Guayabo National Monument (Costa Rica), Los Katios National Park (Colombia), and Río Palenque Science Centre and Tinalandia Reserve (Ecuador). Numbers decline with extensive deforestation.

## 41. Golden-naped Woodpecker

### *Melanerpes chrysosauca*

**French:** Pic masqué **German:** Buntkopfspecht **Spanish:** Carpintero Nuquigualdo  
**Other common names:** Beautiful Woodpecker (*pulcher*)

**Taxonomy.** *Melanerpes chrysosauca* Salvin, 1870, Chiriquí, Panama.

Sometimes placed in a separate genus *Tripsurus*, along with *M. pucherani*, *M. cruentatus* and *M. flavifrons*. Forms a superspecies with first of those, or both sometimes included in the superspecies represented by last two. Distinctive *race pulcher* geographically isolated, sometimes treated as separate species. Two subspecies recognized.

**Subspecies and Distribution.**

*M. c. chrysosauca* Salvin, 1870 - SW Costa Rica to W Panama.

*M. c. pulcher* P. L. Slater, 1870 - NC Colombia (Magdalena Valley).

**Descriptive notes.** c. 17-18 cm; 45-68 g. Male has golden-yellow forehead, occasionally tinged orange, red crown (often some olive-yellow feather bases visible), golden-yellow hindcrown to hindneck; short black-streaked white line just behind eye; black narrowly around eye, across ear-coverts and down neck side; lores, moustachial region, chin and upper throat white, strongly tinged grey-buff at rear and on throat; mantle and scapulars blue-glossed black, narrow white panel down mantle centre, white back to uppertail-coverts often tinged pale buffish; blue-black wing-coverts; brownish-black (blackier towards bases) flight-feathers tipped white when fresh, inner webs with short white bars; uppertail black, outer feathers often with 1 or 2 white bars or spots; lower throat to upper belly olive-buff, washed grey, central belly orange-red, rest of underparts pale buffish-white with broad black arrowhead barring; underwing brownish, coverts blackish, barred white, marginal coverts white; undertail brownish-black; longish bill almost pointed, culmen curved, fairly broad across nostrils, black with paler base; iris brown;

legs grey, sometimes tinged green or brown. Female is slightly smaller, shorter-billed than male, has forehead and forecrown golden-yellow, central crown black (occasionally a few red feather tips), hindcrown to hindneck golden-yellow. Juvenile duller, black areas browner, yellow of forehead paler and less extensive, barring below duller and less contrasting, belly patch smaller and more orange, both sexes with red-tipped feathers on crown, less extensive on female. Race *pulcher* has white on mantle partly or sometimes fully barred black, forehead patch paler buffish or creamy-white and extending to forecrown, barring below extending across upper belly, male with red of crown continuing to upper nape, golden lower nape and hindneck, female with black central crown, red hindcrown, golden nape and hindneck. VOICE. Resonant "churr"; loud, rattling or laughing short trill rapidly repeated 3-5 times on same pitch; also several short rattles; nestlings utter squeaking buzz. Both sexes drum occasionally.

**Habitat.** Humid areas with dense tall rainforest, including edges of clearings, forest edge and plantations enclosed by forest; increasingly extending into semi-open areas with scattered trees as forests shrink. Replaces *M. pucherani* in drier areas in Colombia. From lowlands to 1200 m, locally to 1500 m; from 400 m to 1500 m in Colombia.

**Food and Feeding.** Wood-boring beetles and their larvae, winged termites, also other insects. Takes much fruit: *Cecropia*, figs (*Ficus*), arillate seeds, bananas, oranges, palm fruits; takes fruits from artificial feeders. Forages in pairs or family parties of 3-6 individuals throughout year. Prefers canopy and middle levels of humid forest. Constantly pecks and hammers into decaying trunks and branches. Frequently captures insects on the wing, showing great skill; ascends above treetops to catch these, especially on wet evenings.

**Breeding.** Mar-Jun; rarely, 2 broods in a season. Displays with deep bows accompanied by "churr" calls. Nest-hole excavated by both sexes, 5-30 m up, usually in massive dead trunk, excavation can be completed in 2 weeks. Clutch 3 or 4 eggs, but usually 2 or 3 young fledge; both sexes incubate, in long sessions, both sleep together in nest, incubation period c. 12 days; chicks fed by both parents, apparently more by male, fledging 33-34 days; fledglings cared for by parents for up to 3 months, roost with them in hole until next breeding season; when 2 broods, a juvenile from first brood may also incubate and feed second brood, and roost in same nest.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in South Central American Pacific Slope EBA and Nechí Lowlands EBA. Rather scarce and local throughout range. In Pacific lowlands of Costa Rica, occurs in Caracara Biological Reserve, in Manuel Antonio National Park and in Corcovado National Park.

**Bibliography.** Anon. (1998b), Heisler (1994), Hilty & Brown (1986), Ridgely & Gwynne (1989), Selander & Giller (1963), Short (1985b), Skutch (1948a, 1969a), Slud (1964), Stattersfield *et al.* (1998), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a).

## 42. Yellow-tufted Woodpecker

### *Melanerpes cruentatus*

**French:** Pic à chevron d'or      **German:** Gelbbrauenspecht      **Spanish:** Carpintero Azulado  
**Other common names:** Red-fronted Woodpecker ("*M. rubrifrons*")

**Taxonomy.** *Picus cruentatus* Boddaert, 1783, Cayenne.

Sometimes placed in a separate genus *Tripsurus*, along with *M. pucherani*, *M. chrysauchen* and *M. flavifrons*. Forms a superspecies with last of those, sometimes also including first two. Black-headed morph (mostly in S & SE Venezuela, the Guianas and Amazonian Brazil, where it predominates) was formerly considered a separate species, "*M. rubrifrons*", but interbreeds freely with yellow-tufted morph wherever the two co-occur; hence, there are no grounds even for subspecific division. Population in W & S of range (Colombia to Venezuela and W Brazil, and S of there) described as race *extensus*, on basis of difference in tone and extent of red on belly; this character, however, varies greatly among all populations, and racial separation considered untenable. Monotypic.

**Distribution.** E Colombia and S & SE Venezuela E to the Guianas and NE Brazil (E to Maranhão), S to E Ecuador, E Peru, N & E Bolivia and Mato Grosso.

occasionally tipped white; red on belly centre extending as wedge to lower breast, but depth of colour and its extent considerably variable individually; lower breast sides to sides of belly and undertail-coverts white or pale yellowish-white with bold black arrowhead barring; underwing barred black and white, margins browner; undertail brownish-black; long bill almost pointed, culmen curved, rather broad across nostrils, black; iris pale yellow, very broad orbital skin whitish to pale yellow; legs grey to pinky-grey. Male of yellow-tufted morph differs in having white (often yellow-tinged) supercilium from just in front of eye back to lower nape, golden-yellow or sometimes orangey lower nape and hindneck, red on crown usually more extensive and less rounded in shape. Intermediates between the 2 morphs have restricted or broken supercilium, less yellow on hindneck. Female is slightly shorter-billed than male, lacks red on crown, yellow-tufted female often with less golden-yellow on head. Juvenile duller than adult, black areas much browner, underparts greyer with barring more obscure, belly patch more orange-coloured, both sexes with red in crown centre; juvenile yellow-tufted morph has reduced white and yellow head markings. VOICE. Noisy, with various loud, hoarse calls like those of *M. formicivorus*: single "chowp" notes, and double "r-r-r-aack-up", "rrr-eh" or "churr-dówp" notes; also nine-syllable "ih-ih-ih-ih..." or "tréh-tréh-tréh...", slowing towards end; more rasping variants during display, frequent "kat-sup, kat-sup" calls in bowing ceremony when two birds meet.

**Habitat.** Rainforest, secondary growth, forest edge, and burnt-over clearings with isolated trees; sometimes near houses and even in towns. Tall dead trees seem to be important element of habitat. Sea-level to 1350 m, mostly below 1200 m; locally to 1500 m (e.g. in Ecuador).

**Food and Feeding.** Insects (ants and others) and large quantities of fruits (berries) are main constituents of diet; other arthropods, e.g. spiders and chilopods, also taken. Forages mostly in groups of 3-5 birds, sometimes up to 12 or more. Forages in upper parts of tall, dead trees. Main technique

is gleaning from surface of trunks and branches and from twigs and leaves of canopy; also probes; flycatching common in evening hours.

**Breeding.** Mainly Jun-Aug in E Peru E to the Guianas, from Mar in Colombia, to Sept along R Negro; Mar-Jun in Bolivia and Amazonian Basin to Ecuador; Dec-Feb in SE Peru and Mato Grosso. Communal breeder, with adult helpers; single adult may attend to 3 nests, but other details not known. Various displays include bowing. Nest excavated in dead tree or tall dead stump, sometimes several nests found in fairly close proximity. Clutch size and incubation and fledging periods not documented; nestlings apparently tended by entire social unit, and an adult may feed at several nests; fledglings accompanied by individual or by group.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally common and conspicuous; fairly adaptable. Common in Colombia, Ecuador and Peru. Occurs in numerous protected areas, including Amacayacu National Park (Colombia), Canaima National Park, Imataca Forest Reserve and El Dorado (Venezuela), Cuyabeno Reserve (Ecuador) and Manu National Park (Peru).

**Bibliography.** Allen (1995), Balchin & Toynne (1998), Bloch *et al.* (1991), Bruce *et al.* (1997), Canaday & Jost (1999), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Donahue (1994), Flores *et al.* (2001), Friedmann (1948), Guilherme (2001), Haverschmidt & Mees (1994), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Oniki & Willis (1999), Oren & Parker (1997), Parker *et al.* (1982), Perry *et al.* (1997), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Robinson (1997), Robinson & Terborgh (1997), Short (1985b), Sick (1993), da Silva (1996), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Tostain *et al.* (1992), Willis & Oniki (1990).

## 43. Yellow-fronted Woodpecker

### *Melanerpes flavifrons*

**French:** Pic à front jaune      **German:** Goldmaskenspecht      **Spanish:** Carpintero Arcoiris

**Taxonomy.** *Picus flavifrons* Vieillot, 1818, Brazil.

Sometimes placed in a separate genus *Tripsurus*, along with *M. pucherani*, *M. chrysauchen* and *M. cruentatus*. Forms a superspecies with last of those, sometimes also including first two. Birds from E & S of range, generally much darker below than NW populations, are sometimes separated as race *rubriventris*, but considerable variation exists throughout entire range; recognition of geographical races considered unwarranted. Monotypic.

**Distribution.** E & SE Brazil from Bahia and Goiás S to SE Mato Grosso and Rio Grande do Sul, E Paraguay and NE Argentina (Misiones).

**Descriptive notes.** c. 17 cm; 49-64 g. Male has golden-yellow forehead and forecrown with white feather bases, red central crown to hindneck; glossy blue-black lores, area around eye, and ear-coverts down neck side to mantle; pale yellow to deep golden-yellow cheeks, chin and throat, sometimes to upper breast; blue-black mantle, central feathers with white on one web and black on other (pattern of broad white streaks), white back to uppertail-coverts usually with few black spots (rarely, hint of bars), black shaft streaks on uppertail-coverts; glossy blue-black wing-coverts; black to brownish-black flight-feathers glossed blue on edges, white bars

on inner webs of secondaries and patches on tertials; uppertail black, central feather pair often with 1 or 2 white bars on inner webs, outer feathers tipped white when fresh; pale grey to yellowish-olive-grey lower neck sides and breast, orange to crimson-red belly highly variable in intensity and extent of red, whitish flanks to undertail-coverts (often tinged olive or buff-yellow) with black barring; NW populations generally much paler below than coastal ones, with throat whitish, breast whitish-grey, belly more orange, but considerable variation throughout entire range; underwing brownish, barred white; undertail brown, outer feathers often olive-brown; long bill chisel-tipped, culmen barely curved, fairly broad across nostrils, black; iris blackish to blue-black, broad orbital skin whitish to orange-yellow; legs olive, tinged green or brown. Female is slightly smaller, shorter-billed than male, has crown to hindneck blue-black. Juvenile duller, black areas browner, less glossy, belly patch smaller and more orange, eyes brown, male with red on crown and hindcrown, female generally only on mid-crown. VOICE. Noisy, with strident "kikiki", "tsitidi"; also flight calls sounding like "benedito"; series of "chit" notes when meeting perched conspecific; also "tweewetwee tweewetwee..." apparently in aggression, and "ceek ceek". Drums, usually on tall trees.

**Habitat.** Humid forest; also secondary vegetation, such as cane fields, palm groves, orchards; recorded in partly burnt forest. Sea-level to 1800 m.

**Food and Feeding.** Takes many fruits, berries and seeds; also insects; captives fed sugar water and mealworms. Nestlings fed fruits, especially of *Virola*, also insects, including larger ones such as katydids and dragonflies (Odonata). Stores seeds; caches fruit and insects near nest. Observed in groups; probes in crevices, but details of foraging methods not recorded. Anvils used for breaking up larger food items.

**Breeding.** Jan-Mar in most of range, to Jun in SE Brazil; recorded in Nov in Espírito Santo. Cooperative breeder, up to 4 males and 2 females seen to attend single brood; solitary or in loose colonies. Display with head-waving and head-weaving. One nest was 28 m up in trunk of tall dead tree, attended by 1 male and 3 females, male fed chicks less often than females, 2 females (possibly young helpers) seemed to feed less than the other, feeding often interrupted by bouts of display or arrival of toucans (Ramphastidae), faecal sacs removed frequently, male roosted with young at night; incubation and fledging periods unrecorded; fledglings return to nest to roost. Toucans probably usurp nest-holes and prey on nestlings.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. No information on numbers. Occurs in neighbouring Iguazú and Iguazú National Parks (Brazil/Argentina), Rio Doce State Park and Carlos Botelho State Park (Brazil), and Uruguá-i Provincial Park (Argentina). Ability to exploit secondary habitats may indicate some adaptability, but lack of information on ecology and breeding makes it difficult to assess any possible threats. In SE Brazil (São Paulo), this species plays an important role in the reproduction of the Plain Parakeet (*Brotogeris tirica*) and the Maroon-bellied Parakeet (*Pyrrhura frontalis*), both of which use its abandoned holes as nesting sites.

**Bibliography.** Aleixo & Galetti (1997), dos Anjos (2001), dos Anjos & Schuchmann (1997), dos Anjos *et al.* (1997), Belton (1984), Brooks *et al.* (1993), Buzzetti (2000), Canevari *et al.* (1991), Capper *et al.* (2000), Descourtilz (1983), Dubs (1992), Figueiredo & Lo (2000), Goerck (1999), Guix, Martín & Mañosa (1999), Guix, Tabáñez *et al.* (1992), Hayes (1995), Lowen *et al.* (1995), Machado & Rodrigues (2000), Oniki & Willis (1998), de la Peña (1994), Pereyra (1950), do Rosário (1996), Scott & Brooke (1985), Short (1985b), Sick (1993), da Silva (1996), Soares & dos Anjos (1999), Stager (1961a), Stotz *et al.* (1996), Tobias *et al.* (1993), Yamashita & Lo (1995).

## 44. White-fronted Woodpecker

*Melanerpes cactorum*

French: Pic des cactus German: Kaktusspecht Spanish: Carpintero de los Cardones

**Taxonomy.** *Picus cactorum* d'Orbigny, 1840, near Chaluani and Chilon, Mizqué, Bolivia.

Despite some variation in throat colour (from all white to all yellow), differences not sufficiently constant geographically to warrant recognition of any races. Monotypic.

**Distribution.** SE Peru (Puno), C & SE Bolivia (S from Cochabamba and Santa Cruz) and SW Brazil (SW Mato Grosso) S to W Paraguay and N Argentina (S to La Rioja, San Luis and Entre Rios, E to W Corrientes).**Descriptive notes.** c. 16-18 cm; 29-53 g. Male has white forehead and forecrown, lores, moustachial region and lower ear-coverts; small partly concealed patch of red near front of central crown (sometimes totally concealed); otherwise blue-black from central crown to hindcrown, narrowly around eye and back through upper ear-coverts, continuing down neck side to mantle; white nape faintly tinged buff or yellow, pure white on hindneck; chin and throat white (mostly in S), or partly yellow, or entirely yellow or golden (mostly in Bolivia and W Argentina); glossy blue-black mantle and scapulars, broad white or buff-whitestreaks down mantle centre (feathers with one web white, other black), white back to uppertail-coverts barred or spotted black; black wing-coverts glossed blue, greater spotted and tipped white, medians with black-spotted white distal half; flight-feathers blackish, primaries browner, white bars on both webs of secondaries and tertiaries and on bases of primaries; uppertail black, tipped white (when fresh), all feathers barred white; buff below, belly paler and greyer, lower flanks and undertail-coverts barred; underwing brown, barred white, coverts whiter and unbarred; undertail brownish-black, barred white; relatively short bill almost straight, slightly chisel-tipped, broad across nostrils, black or grey-black; iris brown to red-brown; legs slate-coloured. Female smaller, shorter-billed than male, lacks red spot on crown. Juvenile browner, less glossy above, more barred below, both sexes with some orange-red on crown centre. **Voice.** Loud "weep-weep" and "wee-beep", resembling call of *Sphyrapicus varius*; faster renditions when displaying. Short, weak drumrolls near hole early in breeding season.**Habitat.** Dry forest; frequents forest edge, savanna, gallery forest, bush country (Chaco), montane scrub; associates with cacti (*Cereus*). Also found in palm groves with trees. From lowlands to 1700 m, locally to 2500 m in Bolivia.**Food and Feeding.** Diet includes insects and fruits; ants apparently important, beetles also recorded. Some food cached. During cold dry season (Jun-Sept), regularly drills holes in e.g. mesquite (*Prosopis*) to take exuding sap; in one study in Argentina, sap-feeding comprised 16-83% of observations of foraging in Jun-Jul. Usually in groups of 3-5 birds. Forages on palms, trunks and branches; gleans and probes.**Breeding.** Sept-Dec. Co-operative breeder in groups of up to 5 or more birds; possibly loosely colonial. Bowing displays observed, with much calling. Nest excavated in dead tree, palm or cactus. No other information.**Movements.** Probably some seasonal movements.**Status and Conservation.** Not globally threatened. Reasonably common in much of range; locally very common in Argentina; rare in Peru. Occurs in Chancaní and Monte de las Barrancas Reserves (Argentina). Probably secure, but conservation status difficult to assess in absence of data.**Bibliography.** Blendinger (1999), Canevari *et al.* (1991), Chebez *et al.* (1999), Clements & Shany (2001), Contreras (1980a), Contreras *et al.* (1990), Fjeldsø & Krabbe (1990), Friedmann (1927), Genise *et al.* (1993), Hayes (1995), Lago-Paiva & Willis (1994), López (1997), Mazar Barnett & Pearman (2001), Miserendino (1998), Narosky & Yaurieta (1993), Nellar (1993), Nores *et al.* (1983), Paiva & Willis (1994), Parker *et al.* (1982), de la Peña (1994, 1997), Remsen & Traylor (1989), Remsen *et al.* (1986), Schmitt *et al.* (1997), Short (1975, 1985b), Stotz *et al.* (1996), Strussmann (1998), Wetmore (1926), Yamashita & Lo (1995).

## 45. Hispaniolan Woodpecker

*Melanerpes striatus*

French: Pic d'Hispaniola German: Haitispecht Spanish: Carpintero de la Española

**Taxonomy.** *Picus* [sic] *striatus* P. L. S. Müller, 1776, Santo Domingo, southern Dominican Republic. Monotypic.**Distribution.** Hispaniola and nearby Beata I.**Descriptive notes.** c. 20-24 cm; male 83-92 g, female 65-75 g. Small woodpecker with marked sexual size dimorphism. Male has bright red forehead to upper hindneck, feathers with black bases; rest of head, including forehead and superciliary area, pale buffish-white to greyish, ear-coverts often greyer, chin and throat more olive-buff; lower hindneck broadly striped black and whitish; black upperparts and tertiaries broadly barred greenish-yellow to golden, bars whiter in worn plumage; yellow or greenish-yellow rump, red-tipped feathers on lower rump, often with faint blackish bars; red uppertail-coverts with blackbases; brownish-black primaries and secondaries broadly barred yellowish, bars whiter on primaries; uppertail brownish-black, outer feathers edged whitish; dark reddish-buff below, washed grey, tinged olive on upper breast and belly, occasionally a few red-tipped feathers on belly and/or darker streaks on lower flanks, latter rarely with obscure thin bars; underwing barred brown and white, coverts plain olive; undertail brownish, outer feathers washed yellow; long bill straight, broad, dark grey, blacker tip; iris white to pale yellowish; legs greenish-grey. Female is smaller, less bulky, bill up to c. 21% shorter than male's, has black crown often white-speckled at sides. Juvenile much as adult, but red of nape and tail-coverts more orangey and less extensive, both sexes with white-spotted black crown with few red tips. **Voice.** Highly variable; long series of up to 23 notes in long-distance communication; commonly several connected "waa" notes during encounters, when also

aggressive "wup", more defensive "ta" and "ta-a" calls; also 3-5 distinct notes combined in short "bddd" call. Instrumental signals near hole; drumming infrequent to rare.

**Habitat.** Wooded swamps, mangroves, coastal scrub and semi-arid country in lowlands to humid forest in mountains; also pine (*Pinus*) woodland, and trees and palms in and around villages and towns; most numerous in cultivated areas with trees and palms, especially in hilly areas.**Food and Feeding.** Various insects, especially beetles, Lepidoptera, ants (both adults and pupae), also spiders, scorpions (Scorpiones); lizards (*Anolis*) also recorded. Also fruits, including commercially grown crops (oranges, cacao pods), and seeds, including corn, readily taken; vegetable matter, including tree sap, seems especially important. Occurs in pairs or, often, in groups; particularly large aggregations at fruiting trees. Forages above ground at all levels, mainly 7-20 m, on trees, bushes, vines, poles and cacti. Often hangs upside-down, on twigs and pine cones, and reaches for fruits. Main feeding techniques are pecking, probing and gleaning; also takes insects by hawking; probably excavates sap wells. Probes in crevices and holes, most often in dead substrates; also probes at bromeliads and other large epiphytes, and fruits (to obtain seeds or insects). Females glean c. 1.5 times as much as males, and probe much less frequently (0-6%, compared with 34% for males; difference may be reversed if other types of probing included); males use hammering or pecking twice as much as females. Pecks less forcefully than e.g. *M. aurifrons*. Larger items placed in anvil for treatment.**Breeding.** Breeds in all months, predominantly Feb-Jul. Both solitary and colonial; often loose colonies of 3-20 nests in 1-3 trees, up to 26 recorded in single tree, highest holes apparently occupied by dominant individuals; possibly several helpers but further study needed. Displays include bowing and lateral swinging, gliding with raised wings; courtship feeding recorded. Nest excavated by both sexes, mainly by male, at 2-11 m in dead tree, live or dead palm, cactus, stub, or telephone pole; mean dimensions of entrance 9.7 cm high, 7.9 cm wide; nest-site and prominent perches defended. Clutch 4-6 eggs; incubation and fledging periods apparently not documented; in one study, 4 nestlings fed 15 times by male and 17 times by female in 3-6 hours, average 1 feed every 6-8 minutes; nestlings fed mostly by regurgitation; fledglings fed by parents near nest for at least several days.**Movements.** Resident.**Status and Conservation.** Not globally threatened. Restricted-range species: present in Hispaniola EBA. Common and widespread throughout range. Although this species is currently secure, continuing habitat loss and degradation, and increasing urbanization, could become threats unless adequate legislation is put in place to protect important habitats. Lack of general environmental awareness also a problem. This woodpecker's predilection for fruits and seeds can bring it into conflict with farming interests; sometimes persecuted locally for attacking commercial crops.**Bibliography.** Albaine & Grullón (1981), Anon. (1998b), Ashmole (1967), Bernstein (1964, 1965), Bond (1928, 1985), Cruz (1974a), Delacour & Legendre (1925), Dod (1973, 1977, 1987, 1992), Faaborg (1985), Grullón (1976), Latta & Wunderle (1996), Olson (1972), Raffaele *et al.* (1998), Rimmer *et al.* (1998), Samedy *et al.* (1986), Selander & Giller (1963), Short (1970b, 1974d, 1985b), Stotz *et al.* (1996), Villard (1999a, 2001), Wallace (1969, 1974a), Wetmore & Swales (1931), Wiley & Ottenwalder (1990).

## 46. Jamaican Woodpecker

*Melanerpes radiolatus*

French: Pic de la Jamaïque German: Jamaikaspecht Spanish: Carpintero Jamaicano

**Taxonomy.** *Picus radiolatus* Wagler, 1827, Jamaica.Sometimes combined with other barred congeners in a separate genus *Centurus*. Monotypic.**Distribution.** Jamaica.**Descriptive notes.** c. 24-26 cm; 92-131 g. Male has whitish to buff forehead, red forecrown to hindneck, yellowish lores; rest of head, including superciliary area, and chin to uppermost breast white, rear ear-coverts tinged greyish or olive; upperparts, including wing-coverts and tertiaries, black with thin white to green-tinged white bars, broadest on rump and uppertail-coverts; black flight-feathers, browner on primaries, all but outer primaries with narrow white bars on both webs (broader on inner webs); uppertail black, central feather pair finely barred white on inner (rarely, also outer) webs, outer pair with small white spots or barson outer (and sometimes inner) webs; olive-grey to olive-buff below, feathers tipped greenish when fresh, central belly diffusely yellow to reddish, lower flanks to undertail-coverts black with white to olive-white bars; underwing brownish-black, barred white; undertail brownish-black, outer feathers tinged olive; long bill more or less pointed, culmen curved, fairly broad across nostrils, black; iris red, orbital skin grey to brown; legs slate-black. Female is less bulky than male, has crown grey to dark grey, sometimes buff-tinged or partly black. Juvenile duller than adult, greyer below with yellower belly patch, more diffuse flank bars, brown eyes, both sexes with red on crown, less on female. **Voice.** Most frequently a loud "kaa", sometimes repeated 2 or 3 times; single "kao" calls in mild alarm; very loud "kaaaah" apparently as territorial advertisement; "wee-cha weechea" in intraspecific encounters; also "krirr, krirr" and more intimate "whirr-whirr" during breeding season. Loud drumming, by both sexes, mutual tapping near nest-hole.**Habitat.** Variety of wooded habitats, including mangroves, wooded pastures, lowland copses, citrus groves, coconut plantations, shaded coffee plantations, gardens, also dry and wet limestone forest, mistforest, lower montane rainforest. At highest densities in secondary mesophytic forest. From sea-level to mountains.**Food and Feeding.** Animal prey mostly insects (Orthoptera, Lepidoptera, Coleoptera, also ants), mainly of surface-dwelling species, majority of items 1-10 mm in size; also snails, occasionally lizards (*Anolis*). Vegetable content comprises almost half of all food eaten; includes much fruit, especially of *Cecropia* and *Ficus*, also of *Daphnopsis*. Hunts singly or in pairs. Forages mostly at mid-crown level; visits lower and upper canopy, and vines. Seeks food on trees, particularly in bromeliads and other epiphytes; rarely searches on trunks more than c. 10 cm in diameter. Predominant techniques are snatching (for fruit) and probing, followed by pecking (c. 15%), gleaning, and aerial feeding; no clear differences between sexes in foraging behaviour. Reported to peck at sugar canes to extract juice. Larger items broken up in anvil, before being swallowed or fed to chicks.**Breeding.** Dec-Aug, sometimes in other months; laying Jan to early Jul; sometimes 2 or even 3 broods in a season. Monogamous; solitary. Nest excavated at 5-15 m in trunk or branch of dead tree or dead branch of live tree, or in utility pole, male doing two-thirds of work; mean dimensions of entrance hole 7.2 cm high, 6.8 cm wide; radius of 40 m around nest defended, but no interspecific aggression recorded, and even potential nest-hole competitors not attacked. Clutch 3-5 eggs, laid at

daily intervals; incubation by both sexes, only male at night, period 13 days; chicks brooded equally by both sexes, fed at average of 10.3 visits per hour, peak feeding during days 10-20 of nestling period, male feeding slightly more than female; in one observation totalling 6.4 hours, however, male fed 38 times, female 68 times, average 1 feed per 3.6 minutes; fledging period c. 1 month; fledglings accompanied by parents for at least 1 further month. Reproductive success adversely affected by usurpation of nest-hole by Common Starlings (*Sturnus vulgaris*).

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Jamaica EBA. Very common throughout the island. No data on population size. Home ranges of pairs overlap; highest recorded densities 0.91 individuals/ha, in secondary mesophytic forest. Main potential threat is habitat loss; although many forest areas are protected, enforcement of laws is often non-existent. Programmes to provide the human population with reliable information on environmental matters would help considerably in the conservation of this and other species in Jamaica.

## 47. Golden-cheeked Woodpecker

### *Melanerpes chrysogenys*

**French:** Pic élégant      **German:** Goldwangenspecht      **Spanish:** Carpintero Cariamarrillo  
**Other common names:** Gold-cheeked Woodpecker

**Taxonomy.** *Picus chrysogenys* Vigors, 1839, no locality; probably Mazatlan, in Sinaloa, or San Blas or Tepic, in Nayarit, western Mexico.

Sometimes combined with other barred congeners in a separate genus *Centurus*. Variation clinal; population in interior (Morelos, adjacent Michoacán) often separated as race *morelensis*, tending to be paler with less yellow and orange than *flavinuchus*, but considerable overlap exists with latter in plumage characteristics. Two subspecies recognized.

**Subspecies and Distribution.**

*M. c. chrysogenys* (Vigors, 1839) - W Mexico from S Sinaloa to Nayarit.

*M. c. flavinuchus* (Ridgway, 1911) - Jalisco E to SW Puebla and SE along coast to E Oaxaca.

**Descriptive notes.** 19-22 cm; 55-88 g. Male has whitish forehead with golden-yellow at base of bill, red crown (usually becoming more golden-orange on nape), bright yellow-gold hindneck; broad black area encircling eye; deep golden-yellow band from lower lores to ear-coverts, broad buffish to yellow-

buff area below this; golden-buff chin and throat; black upperparts barred white, rump and uppertail-coverts more black-barred white; black wing-coverts with large white spots and tips; black secondaries and tertials barred white; black primaries thinly edged and tipped white (when fresh), bases barred white and forming patch about half-way along; uppertail black, central feather pair broadly barred white, third pair sometimes with a few bars, fourth with half-bars, outer pair fully white-barred; grey-brown to brownish-buff underparts strongly washed olive-yellow (yellowish feather tips), central belly with variably sized yellowish-orange patch, lower

parts becoming paler and greyer, flanks to undertail-coverts with dark bars; underwing brown, barred white, white patch on primaries; longish bill barely chisel-tipped, culmen curved, rather broad across nostrils, black; iris reddish to orange-brown, orbital skin blackish; legs green-grey. Female is slightly shorter-billed than male, has crown greyish-buff, often with some darker feathers, nape orange-red. Juvenile is browner or greyer above with less contrasting bars, paler and greyer below with strong yellow suffusion, obscure bars in lower regions, both sexes with red on crown, female less red and often much black in crown. Race *flavinuchus* is slightly larger and duller, greyer below, has less yellow on face, more yellow instead of red on hindneck. **Voice.** Many churring calls and short series of notes, e.g. nasal "ki-di-dik", more explosive than call of *M. uropygialis*; loud, nasal "cheek-oo, cheek-oo, cheek-oo, keh-i-heh-ek", softer "keh-i-heh" or "kuh-uh-uh".

**Habitat.** Mesic to xeric forest and edge, forest patches, open areas with scattered trees and plantations. Restricted to Pacific slope and plain, from sea-level to c. 1500 m.

**Food and Feeding.** Insects, including adults and larvae of beetles, ants; also various fruits and seeds. Forages singly and in pairs, at middle and upper levels, on trees. Feeding techniques are gleaning, probing and pecking. No further details available.

**Breeding.** May-Jul. Nest-hole in tree or cactus. Clutch size and other aspects of breeding undescribed.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common to fairly common; widespread within range, recorded at numerous sites. A little-known species. Research required on its ecology and breeding biology. No known threats.

**Bibliography.** Anon. (1998b), Binford (1989), Friedmann *et al.* (1957), Howell & Webb (1995), Hutto (1980, 1992), Peterson & Navarro-Sigüenza (2000), Schaldach (1963), Selander & Giller (1963), Short (1985b), Stotz *et al.* (1996).

## 48. Grey-breasted Woodpecker

### *Melanerpes hypopolius*

French: Pic alezan German: Graukehlspiecht Spanish: Carpintero Pechigrís  
Other common names: Balsas Woodpecker

**Taxonomy.** *Picus hypopolius* Wagler, 1829, Tehuacán and Tecuapán, Puebla, Mexico. Sometimes combined with other barred congeners in a separate genus *Centurus*. Possibly closer to *M. lewis*, *M. formicivorus* and *M. erythrocephalus*. Formerly considered conspecific with *M. uropygialis*. Monotypic.

**Distribution.** Interior of SW Mexico from N Guerrero and Morelos E to EC Oaxaca.

**Descriptive notes.** c. 19–21 cm; 46–54 g. Male has white to buffish-white forehead, red patch on central crown, narrow area of black around eye, a few red feathers beneath eye and sometimes also in moustachial region (red occasionally absent); rest of head and neck to upper mantle pale buff-brown to grey-brown, rear ear-coverts often slightly darker, malar usually paler or whitish; black upperparts and wing-coverts barred white to buffish-white, white rump and uppertail-coverts with black spots, streaks or bars; black flight-feathers broadly barred white, primaries also tipped and edged white and with white bars sometimes forming

patch near base; uppertail black, tipped white (fresh), central feather pair with large white spots on inner webs, outer pair barred white on outer webs; grey-brown below, becoming paler with variable black arrowhead bars on lower underparts; underwing brown, barred white, white patch at base of primaries; fairly long bill slightly chisel-tipped, culmen curved, fairly broad across nostrils, blackish with paler lower mandible; iris reddish to brown, orbital skin grey to whitish; legs grey. Distinguished from *M. uropygialis* by smaller size, somewhat greyer plumage, red beneath eye, stronger white bars above. Female resembles male, but lacks red on crown. Juvenile is duller, browner and greyer, barring less contrasting, both sexes with dark red on crown. Voice. Variable calls include nasal “yek-a yek-a”, e.g. during interactions; series of usually 4 dry rattling “chi-i-i-i-r” chirps; nasal “chuck” repeated 2–4 times, often by female near nest; voice generally lower-pitched and harsher than that of *M. aurifrons*. Drums loudly, mostly when intruder present.

**Habitat.** Xeric areas with scattered trees, shrubs, or large cacti, also agricultural areas; extends into riverside groves, but avoids these if *M. chrysogenys* present. Hills, between 900 m and 2100 m.

**Food and Feeding.** Fruits, including those of *Ziziphus* and cacti (e.g. *Opuntia*); also insects, including termites (Isoptera), cicadas (Cicadidae). Some food stored. Generally observed in groups of 3–10 individuals. Forages at various levels, descends to ground. Flycatching frequent; sallies from top of cactus, mostly upwards but also in downward swoops, with skilful aerial manoeuvres. Also probes in cactus flowers, bromeliads; gleaning and digging apparently rare. Uses anvils, both natural cracks and excavated ones.

**Breeding.** Breeds from late Apr to Jul. Co-operative, colonial breeder; at one site, 3 nests with 5 males and 3 females present. Nest-hole built in tree or, frequently, at 3–6 m in cactus. Clutch size and incubation and fledging periods not recorded; in one study, peak of brood-feeding in early afternoon, up to 40 feeds per hour, males provided more frequent feeds than did females; fledglings spent most of time concealed within cacti.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Balsas Region and Interior Oaxaca EBA. Common to fairly common throughout range; uncommon in some places (e.g. C Oaxaca). A very poorly known species. Study needed to determine its ecology and breeding biology. No known threats.

**Bibliography.** Anon. (1998b), Binford (1989), Friedmann *et al.* (1957), Hendricks *et al.* (1990), Howell & Webb (1995), Hunn *et al.* (2001), Leonard (2000), Peterson & Navarro-Sigüenza (2000), Rowley (1984), Selander & Giller (1963), Short (1985b), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

## 49. Yucatan Woodpecker

### *Melanerpes pygmaeus*

French: Pic de Yucatan German: Yucatanspiecht Spanish: Carpintero Yucateco  
Other common names: Red-vented Woodpecker

**Taxonomy.** *Centurus rubriventris pygmaeus* Ridgway, 1885, Cozumel Island, Mexico. Sometimes combined with other barred congeners in a separate genus *Centurus*. Forms a superspecies with *M. rubricapillus*, and sometimes treated as conspecific, but geographical isolation, combined with minor morphological differences, supports allopatric treatment. Three subspecies recognized.

**Subspecies and Distribution.**

*M. p. rubricomus* J. L. Peters, 1948 - Yucatán Peninsula S to C Belize.  
*M. p. pygmaeus* (Ridgway, 1885) - Cozumel I (off E Yucatán Peninsula).  
*M. p. tysoni* (Bond, 1936) - Guanaja I (off N Honduras).

**Descriptive notes.** c. 16–18 cm; 35–43 g. Male has golden to golden-orange lower forehead, lores, front of moustachial region and chin, buffish-white upper forehead, forehead and supercilium, bright red central crown to hindneck; rest of head and throat buff-brown, tinged grey; black mantle, scapulars and back narrowly barred whitish, white lower back to uppertail-coverts rarely with a few black streaks or bars; black upperwing and wing-coverts narrowly barred white, browner primaries tipped white (when fresh) with bars restricted to bases; uppertail black, outer feathers barred or spotted white on outer webs;

buffish-brown below, variably sized red patch in centre of belly, flanks to undertail-coverts variably barred black; underwing brown, barred white; long bill almost pointed, culmen curved, broad across nostrils, blackish; iris red to brown; legs grey. Distinguished from very similar *M. rubricapillus* by darker underparts more barred on flanks, more extensive golden coloration on face, longer tail. Female is slightly shorter-billed than male, has red on head restricted to nape and hindneck often duller. Juvenile duller, barring above less contrasting, belly patch paler, head pattern less well defined, male with red crown to hindneck, female with blackish crown often barred and occasionally with traces of red. Race *rubricomus* is slightly larger than nominate, paler, has flanks less barred; *tysoni* is larger-billed, has forehead less golden or orange, less golden-yellow on face, usually more white in tail, red on head of male usually broken by buff-brown at rear. Voice. Soft rolling “churr, pyurr-r-r”, also dry laugh e.g. “chuh-uh-uh-uh-uh” or “keh heh heh-heh heh-heh heh-heh”; vocalizations generally softer and less nasal than those of *M. aurifrons*.

**Habitat.** Deciduous forest, edge, clearings, second growth, coastal scrub. Generally at lower elevations than those used by *M. aurifrons*.

**Food and Feeding.** Diet not documented. Forages at lower levels than sympatric congeners. In other aspects, probably very similar to *M. rubricapillus*.

**Breeding.** Breeds Apr–May. No other details available.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common within relatively small range. Occurs in Dr Alfredo Barrera M. Botanical Garden, Quintana Roo. Very poorly known. Research required to establish its ecology and breeding biology. No current known threats.

**Bibliography.** Anon. (1998b), England (2000), Friedmann *et al.* (1957), Gómez de Silva (1998), Howell & Webb (1995), Klaas (1968), Monroe (1968), Paynter (1955), Selander & Giller (1963), Stotz *et al.* (1996).

## 50. Red-crowned Woodpecker

### *Melanerpes rubricapillus*

French: Pic à couronne rouge German: Rotkappenspiecht Spanish: Carpintero Coronirrojo  
Other common names: Little Red-headed Woodpecker; Wagler’s Woodpecker (Panama)

**Taxonomy.** *Centurus rubricapillus* Cabanis, 1862, Barranquilla, Colombia.

Sometimes combined with other barred congeners in a separate genus *Centurus*. Forms a superspecies with *M. pygmaeus*, and sometimes treated as conspecific, but geographical isolation, combined with minor morphological differences, supports allopatric treatment. Hybridizes with *M. hoffmanni* in C Costa Rica. Rather variable; population of SW Costa Rica described as race *costaricensis*, but now considered indistinguishable from nominate; relatively large and dark birds from Margarita I, NE Venezuela and Tobago named as race *terricolor*, but identical individuals occur in other parts of species’ range. In addition, race *paraguanae* may be invalid, as some individuals in E parts of range exhibit similar characteristics. Name “wagleri”, originally applied to birds from Panama, is junior synonym of *rubricapillus*. Four subspecies recognized.

**Subspecies and Distribution.**

*M. r. rubricapillus* (Cabanis, 1862) - SW Costa Rica E to N & C Colombia, Venezuela (except S), Tobago, W Guyana and coastal Surinam.  
*M. r. subfuscus* Wetmore, 1957 - Coiba I (SW Panama).  
*M. r. seductus* Bangs, 1901 - San Miguel I (SE Panama).  
*M. r. paraguanae* (Gilliard, 1940) - Paraguaná Peninsula (NW Venezuela).

**Descriptive notes.** c. 16–18.5 cm; 40–65 g. Male has pale yellow nasal tufts and lower forehead, whitish upper forehead, bright red crown becoming more orange-red on nape and hindneck (some with grey-brown nape); rest of head greyish-buff, lores, side of forehead and chin paler, rarely with faint yellow on chin, lores and malar region; black mantle, scapulars and back barred white, white lower back to uppertail-coverts; black upperwing and wing-coverts barred white, browner primaries tipped white (when fresh) with bars only at bases and forming white patch; uppertail black, central feather pair white with black spots at tip, outer

pair barred white on outer webs; variable below, typically buffish-grey to grey-buff, sometimes darker, washed olive or yellowish (when fresh), paler in lower regions, central belly diffusely reddish to orange-red, lower flanks to undertail-coverts barred black; underwing brown, barred white, white patch at base of primaries; undertail brownish-black, outer feathers washed yellow, markings as above; longish bill slightly chisel-tipped, culmen curved, fairly broad across nostrils, blackish; iris red to brown, orbital skin grey-brown; legs grey. Differs from *M. pygmaeus* in patterning of face and underparts, and in shorter tail; from *M. hoffmanni* in smaller size, darker coloration, reddish (not golden) nape and belly patch. Female has slightly shorter bill than male, crown pale grey-buff to whitish, nape and hindneck reddish to orange-red. Juvenile duller and browner, nape and hindneck paler or yellowish, bars above less contrasting, underparts often slightly streaked, belly patch paler and usually mottled, male with red on crown duller, female with dark crown often barred and occasionally with some reddish tips. Race *subfuscus* is marginally smaller than nominate, typically much darker below, breast and sides deep grey-brown; *seductus* is shorter-winged, has breast a shade darker, female has more red on nape; *paraguanae* is longer-tailed, has paler yellow on forehead, buff-brown nape, yellower hindneck, white bars above broader, belly patch more golden-yellow, female with nape and hindneck pale orange-brown. Voice. Typical calls often wavering and protracted with abrupt terminal note, e.g. “churr, churr, krr-r-r-r”, also various other calls, e.g. “wicka, wicka” in display, similar to those of *M. carolinus* and *M. hoffmanni*; chattering calls like those of Boat-billed Flycatcher (*Megarhynchus pitangua*). Both sexes drum during breeding season, rolls slower than in *M. carolinus*; mutual tapping at nest-hole.

**Habitat.** Deciduous forest, edge, clearings, second growth, coastal scrub, plantations, gardens, also mangroves. Replaced by *M. pucherani* in more wooded areas. Lowlands to 1700 m; to 1900 m in N Venezuela.

**Food and Feeding.** Diet includes ants, beetles, grubs, Orthoptera, other small insects, also spiders; wood-boring larvae of minor importance. Also eats many fruits and berries, including papayas (*Carica*), cashews and bananas; visits balsa flowers for nectar. Generally less dependent on arthropods than e.g. *M. hoffmanni*. Observed frequently in pairs. Forages at various heights, with preference for middle

and lower levels. Feeding techniques include hammering into bark, probing, gleaning from trunks, branches and foliage, and reaching for fruits; pierces the skin of larger fruits to obtain contents. Readily takes fruit from feeders. Larger items are secured in crevice and processed by pecking.

**Breeding.** Feb-Jul in Costa Rica and Panama, May-Jun in Colombia, May-Nov in Venezuela and Mar-Jul on Tobago; sometimes double-brooded. Monogamous, in pairs throughout year; solitary breeder. Nest-hole excavated by both sexes, 3-23 m up in slender dead tree or branch, or in large cactus or sometimes fence post, or may use roost-hole of male; territorial, but nest-hole often lost in competition with *M. chrysolaus* and *tytars* (*Tityra*). Clutch 3-4 eggs, but usually only 2 young reared; incubation 10 days, by both sexes, only male at night; chicks fed and brooded by both parents, fledging period 31-33 days; fledglings cared for by parents for c. 1 month.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. A common and conspicuous woodpecker, widespread within its range. Common to abundant in Costa Rica and Panama; common in Colombia; common in Venezuela and on Tobago. Occurs in Manuel Antonio and Corcovado National Parks (Costa Rica), and Henri Pittier and Morrocoy National Parks (Venezuela). May benefit from forest clearance; numbers tend to increase in areas where thinning and clearance creates more open woodland. Is considered a nuisance locally in plantations and gardens because of its fruit-eating habits.

**Bibliography.** Anon. (1998b), Blake (1958), Bond *et al.* (1989), Friedmann & Smith (1950), Goossen (1989), Haverschmidt & Mees (1994), Heister (1994), Herklots (1961), Hilty & Brown (1986), Kilham (1972c), Meyer de Schauensee & Phelps (1978), Olson (1997), Otvos (1967), Ridgely & Gwynne (1989), Selander & Giller (1963), Short (1985b), Skutch (1969a), Stad (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Varty *et al.* (1986), Vere *et al.* (2000), Villard (1999a), Wetmore (1939, 1957, 1968a).

## 51. Gila Woodpecker

### *Melanerpes uropygialis*

French: Pic des saguaros

German: Gilaspecht

Spanish: Carpintero del Gila

**Taxonomy.** *Centurus uropygialis* Baird, 1854, Bill Williams Fork of Colorado River, Arizona, USA. Sometimes combined with other barred congeners in a separate genus *Centurus*. Formerly considered conspecific with *M. hypopolius*. Interbreeds to limited extent with *M. aurifrons* in SW Mexico. Geographical races poorly differentiated owing to rather marked degree of individual variation; dark birds from S Sonora, SW Chihuahua and N Sinaloa often separated as race *fuscescens*, but probably better treated as part of nominate or, since many appear indistinguishable from *cardonensis*, should perhaps be merged with latter; further study needed. In addition, described races *albescens* (from S Nevada and SE California to NW Sonora), *tiburoniensis* (from Tiburon I, off W Sonora) and *sulfuriventer* (from S of range, S from Sinaloa and Zacatecas) fall within range of variation of nominate, with which they are therefore synonymized. Three subspecies recognized.

**Subspecies and Distribution.**

*M. u. uropygialis* (Baird, 1854) - SE California (Imperial Valley, lower Colorado Valley) and extreme S Nevada E to extreme SW New Mexico, and S in W Mexico to Jalisco and Aguascalientes. *M. u. cardonensis* (Grinnell, 1927) - N & C Baja California.

*M. u. brewsteri* (Ridgway, 1911) - S Baja California (S from San Ignacio).

**Descriptive notes.** 21.5-24 cm; 51-81 g. Male has small red patch in centre of forehead, buffish (rarely, pale yellow) nasal tufts, usually whitish-buff forehead and upper lores and occasionally also chin, sometimes yellow-tinted hindneck; rest of head typically pale grey-brown, variably paler or darker, this colour extending to uppermost mantle and over most of underparts; black upperparts barred white (or bars grey-buff on uppermost mantle), rump mainly white with narrow black bars, uppertail-coverts white with narrow black bars; black wing-coverts, tertials and secondaries barred white, brownish-black primaries tipped white (when

fresh) and with white bars at bases forming patch; uppertail black, tipped white when fresh, central feather pair barred white on inner webs and often with white streak near shaft on outer webs, outer feathers barred white, fourth pair white-barred on tip of inner webs and edge of outer webs; yellow to golden-yellow patch on central belly, lower underparts paler with arrowhead bars; white underwing-coverts barred black; long bill barely chisel-tipped, culmen curved, fairly broad across nostrils, blackish; iris deep red; legs blue-grey to grey. Differs from *M. hypopolius* in larger size, no red beneath eye. Female is smaller, less bulky, shorter-billed than male, lacks red on crown. Juvenile duller, has white bars above more buff-tinted, flank bars more diffuse, belly patch paler, throat often faintly streaked or barred, crown usually dark-barred, male with some red on crown. Races vary mainly in darkness of head and underparts and width of black bars above, but much individual variation: *brewsteri* is very like nominate, but smaller, has longer bill, on average narrower barring above, more numerous black markings on rump; *cardonensis* typically has darker head and underparts, heavier black barring above, but sometimes less dark. Voice. Noisy, with wide range of variable calls; rolling vibrato "chürr üh-rr" often in short series, notes varying in length, 0.18-0.38 seconds, as contact between pair-members and as territorial advertisement, most frequently by male; more rasping versions, e.g. "rruk-rruk", when more agitated; raucous laugh, "geet geet geet geet geet"; high squeaky "kee-u kee-u kee-u"; series of sharp "pip pip" in alarm, more often by female. Both sexes drum occasionally, female even less so, long regular rolls, especially in pre-nesting period.

**Habitat.** Arid habitats with large cacti or scattered trees, including deserts; also mesic habitats such as riparian woodland, subtropical forest, plantations; also occurs around habitations, and visits gardens. Lowlands to c. 1000 m, to 1600 m in far S of range.

**Food and Feeding.** Essentially omnivorous. Animal food includes insects of various kinds, especially ants, beetles, Orthoptera, termites (Isoptera), cicadids, Lepidoptera, Hemiptera, also larvae; also eggs and chicks of other birds, occasionally earthworms and lizards. Wide range of non-animal food, particularly fruits of cacti, especially saguaro cactus (*Carnegiea gigantea*), and berries, mainly of *Lycium* and mistletoes (*Phoradendron*); also seeds, including corn and acorns, latter occasionally stored, and nuts; honey and sugar water taken from feeders, and observed to feed young with pieces of bark or seeds soaked in syrup. Accepts household scraps of all kinds. Hunts singly or in pairs. Forages at all levels, from treetops, cacti and bushes to the ground. Very versatile in its foraging techniques, uses gleaning, reaching, probing and pecking; also taps on trees.

**Breeding.** Apr-Aug; often 2 or 3 broods in a season. Monogamous, in pairs throughout year; solitary nester. Nest-hole excavated by both sexes, at 1-10 m in cactus, tree or palm, when in living cactus used only after drying out; entrance often not circular, average c. 5-7 cm high and 6-3 cm wide, mean cavity depth 27-8 cm; hole reused for several years; territorial, aggressively defends radius of 40-50 m around nest-hole. Clutch 2-7 eggs, mostly 3-5, later clutches smaller; both sexes

incubate, period c. 13 days; both also feed young, in one study hourly feeding rate of male c. 8 and of female 12; fledging period c. 4 weeks; fledglings fed by parents for lengthy period, family group remaining in territory until juveniles disperse or are driven away prior to subsequent breeding attempt; at least occasionally, young from first brood remain with parents during rearing of second brood. Recorded longevity at least 7 years 9 months.

**Movements.** Resident; occasionally wanders short distances N or NW in California (as far W as Los Angeles area). In non-breeding season, some local movements to areas where food sources abundant. **Status and Conservation.** Not globally threatened. Common to fairly common in all suitable habitats in its range. A mid-1980's study in Tucson (Arizona) gave densities of 29 birds/km<sup>2</sup> in urban areas with plenty of native vegetation, 16 birds/km<sup>2</sup> in urban areas with high percentage of exotic vegetation, 9 birds/km<sup>2</sup> in natural desert, and 5 birds/km<sup>2</sup> in urban parks and cemeteries with exotic vegetation; native vegetation a highly important factor, but urbanized areas had higher densities of this species than did areas without houses. Population in USA stable or declining; estimated numbers in riparian habitats in Arizona c. 650 birds in 1976, then 600 in 1983, and 561 in 1986. Significant recent decline in SE California possibly associated with clearing of woodlands, possibly also a result of competition for nest-sites from introduced Common Starling (*Sturnus vulgaris*); further increase in starling numbers might seriously threaten the woodpecker's future survival in some places. Holes produced by this picid provide quarters for many other bird species, as well as mammals and reptiles, which also compete with it for nest-sites. This woodpecker is likely to be important seed disperser of saguaro cactus. Main conservation priorities are ensuring protection of native vegetation in its habitat, and keeping a check on starling populations.

**Bibliography.** Antevs (1948), Baicich & Harrison (1997), Bent (1939), Braun (1969), Brenowitz (1978a, 1978b), Brush *et al.* (1990), Christensen (1971), Cornett (1986), Edwards & Schnell (2000), Friedmann *et al.* (1957), Howell & Webb (1995), Hunter (1984), Hutto (1980, 1992), Inouye *et al.* (1981), Kaufman (1996), Kemlage *et al.* (1981), Kerpez (1986), Kerpez & Smith (1990a, 1990b), Koenig (1986, 1987), Korol & Hutto (1984), Larsen (1987), Larson (1996), MacRoberts & MacRoberts (1985), Martindale & Lamm (1984), McAuliffe & Hendricks (1988), Price *et al.* (1995), Root (1988), van Rossem (1942), Selander & Giller (1963), Short (1985b), Small (1994), Speich & Radke (1975), Wilbur (1987).

## 52. Red-bellied Woodpecker

### *Melanerpes carolinus*

French: Pic à ventre roux

German: Carolinaspecht

Spanish: Carpintero de Carolina

**Taxonomy.** *Picus carolinus* Linnaeus, 1758, North America = South Carolina.

Sometimes combined with other barred congeners in a separate genus *Centurus*. Forms a superspecies with *M. superciliosus*. Interbreeds to limited extent with *M. aurifrons* in S USA (Texas). Individual variation considerable, but considered not sufficiently correlated to any geographical pattern to warrant recognition of races; examination of extensive series of specimens indicates that width of white bars above varies clinally, increasing from E to W. Described race *zebra* from W of range indistinguishable. Birds from S Florida described as race *perplexus*, being slightly smaller and tending to show more white on upperparts, paler red on lower forehead and less white in tail, possibly sufficiently distinct to be separated; birds from E & C Texas described as race *harpaceus*, with greyer cheeks and throat, perhaps also warrant subspecific status; further study required. Monotypic.

**Distribution.** SE North America from SE North Dakota, C Minnesota and N Wisconsin E to extreme S Ontario and S Massachusetts, and S through E USA (W along valleys of R Missouri and R Platte to C South Dakota and extreme NE Colorado) to coastal SC Texas and Florida.

**Descriptive notes.** c. 24 cm; 56-91 g. Male has pinkish to reddish-orange lower forehead, bright red upper forehead and crown to hindneck and uppermost mantle (rarely, nape or hindneck more orange or, exceptionally, yellowish), occasionally some grey feathering across central upper forehead; rest of head, including chin and throat, and short supercilium, grey to whitish-grey, with variably strong orange or pinkish tinge from lores to cheeks and chin; black upperparts barred white, white rump with variable black streaks and bars, white uppertail-coverts sometimes with a few indistinct black streaks or U-shaped markings; black wing-coverts, secondaries and tertials

with white bars or spots, black primaries with large area of white at base forming patch; uppertail black, central feather pair with white on inner webs, outer pair barred black and white on outer webs; all flight-feathers and rectrices tipped white in fresh plumage; pale grey below, breast tinged olive, buffish or pink, central belly pale red or pink (sometimes orange) and bordered by diffuse yellowish wash, lower flanks to undertail-coverts with black V-shaped markings; underwing grey, white primary patch, coverts barred grey and white; long bill slightly chisel-tipped, culmen curved, fairly broad across nostrils, black; iris deep red to red-brown; legs grey to green-grey. Differs from *M. superciliosus* in smaller size, shorter bill, redder upper forehead, less buff underparts. Female is somewhat smaller than male, has upper forehead and crown grey (occasionally small red central patch), normally less extensive reddish colour on cheeks, less reddish suffusion below, often smaller or paler belly patch. Juvenile has barring above less contrasting than on adult, is darker below with variable streaking on breast and usually more extensive but diffuse barring in lower regions, belly patch often indistinct, has brown eyes, male with smaller paler red patch on crown and nape than adult, crown mostly grey with black bars (occasionally, entirely blackish), female with even less red on nape but small area of red on crown. Voice. Highly vocal; calls include vibrato "churr" calls, singly or in series of up to 4 notes, as contact, also in association with other vocalizations and drumming; long series of harsh, low-pitched notes, "cha-aa-ah", typically in territorial conflict; highly variable "chip" or "chup" as single notes or sometimes in series up to 8 seconds long, in alarm or agitation; "chee-wuk" or "wuck-ah", also in long series, in close-contact aggression; quiet "grr" notes in more intimate contacts. Drums in weak rolls, steady rhythm, sometimes a single introductory strike separated by longer interval from following ones; mutual tapping at nest-hole.

**Habitat.** Mesic habitats with dead trees, including swampy woods, open deciduous or mixed coniferous woodland with very large trees, and pecan (*Carya*) groves, also heavy woods of oak (*Quercus*) and elm (*Ulmus*) along rivers and creek bottoms; also longleaf pine (*Pinus palustris*) savanna in E Texas; also shade trees and dead trees in residential areas. Both foraging and nesting habitats tend to be denser with more developed understorey than those used by sympatric woodpeckers, e.g. *M. erythrocephalus*. From sea-level to 600 m, locally to 900 m.

**Food and Feeding.** More or less omnivorous. Animal food mostly arthropods, especially beetles, ants, Orthoptera, Hemiptera, flies, caterpillars, other larvae including some wood-boring ones, also spiders; bigger animal items are tree-frogs, *Anolis* lizards, and bird eggs and nestlings. Great variety of fruits (e.g. apples, peaches, oranges) taken, and berries from many different plants, including

poison-ivy (*Toxicodendron radicans*), hawthorn (*Crataegus*) and others. Seeds and nuts major food in winter; stores acorns, pine seeds, nuts of pecan, hazel (*Corylus*) and beech (*Fagus*); corn important locally. Also takes sap from tree wounds or from wells made by sapsuckers (*Sphyrapicus*); drinks nectar from blossoms. Wide range of items accepted at feeders. In study of diet over all months, plant material constituted 69% of diet and animal food 31%; by season, plant material 82% in winter, 44% in late spring, 60% in summer, 83% in autumn. In C Illinois, winter diet 94% vegetable matter, 6% animal. Usually forages solitarily. Prefers upper storeys of live and dead deciduous trees, particularly oaks, favouring branches 10-30 cm in diameter; dead substrates constitute a third to more than half of those visited, but relative use of these dependent on local availability. Surface probing is most frequent technique, with some pecking and hammering; gleaning is main foraging method during breeding season; also uses aerial flycatching on occasion, but far less than *M. erythrocephalus*. Sexual differences in foraging not always marked; most pronounced in winter, when males more often search trunks for arthropod food. Stores mast in autumn through to early winter, single food items usually cached in crevices; insects and fruit also occasionally cached.

**Breeding.** Late Mar to Aug; occasionally 2 or 3 broods in a season in S. Monogamous, 1 report of possible polygyny; solitary. Nest excavated by male, helped by female towards end of work, at 2-18 m in usually dead tree, or dead branch of live tree, or in fence post or pole, mean size of entrance hole 5.7 cm tall, 5.9 cm wide, cavity depth 22-32 cm; usually new cavity dug each season, but sometimes male's roost-hole used. Female often initiates copulation by mounting male, even after eggs laid. Clutch 2-8 eggs, usually 4-6, laid at 1-day intervals; both parents incubate, only male at night, period 12 days; both also feed chicks, combined rate up to 45 feeds per hour; both sexes brood chicks, female more during day, only male overnight; faeces removed throughout almost entire nestling period; fledging period c. 22-27 days; fledged brood usually divided between parents, and accompanied for up to 6 weeks, occasionally longer; period of dependence shorter, 2-3 weeks, if another brood attempted. Few data on breeding success; in Kansas, 55% of eggs laid produced fledglings; nest contents preyed on by *M. erythrocephalus*, *Dryocopus pileatus* and Common Starling (*Sturnus vulgaris*), and by snakes (*Elaphe*). In captivity, first breeding at 1 year. Recorded longevity in wild 12 years 1 month.

**Movements.** Mostly resident; at least during severe winters, however, N populations may withdraw to S. Generally, tends to concentrate in favourable areas in winter, when sometimes more common in places where rare or absent in summer. Recorded irregularly outside normal range, N to S Saskatchewan, C Ontario, S Quebec and Nova Scotia, W to Idaho and E New Mexico.

**Status and Conservation.** Not globally threatened. Common in most of range; the commonest picid in S of range. Densities in preferred habitats can reach almost 1 bird/ha. In Texas, one of the most numerous bird species in combined forest habitats (bottomland hardwood, mixed pine-hardwood, long pine savanna); one of most abundant species in Mississippi Valley and floodplain. Significant increase recorded in N since mid-1960's. Was formerly shot as a pest in commercial orchards and pecan plantations; nowadays considered only a minor nuisance and generally tolerated. Adaptable, and able to flourish in most types of woodland, including in urban areas; not shy of humans. Suffers competition for nest-sites from other woodpeckers, especially the more dominant *M. erythrocephalus*, also with Common Starling, but population size seems essentially unaffected by this. No known threats.

53. West Indian Woodpecker

*Melanerpes superciliaris*

**French:** Pic à sourcils noirs      **German:** Bahamaspecht      **Spanish:** Carpintero Antillano  
**Other common names:** Great/West Indian Red-bellied Woodpecker; Bahama Woodpecker (*nyeuanus, blakei*); Cayman Woodpecker (*caymanensis*); Cuban Red-bellied Woodpecker (*superciliaris*)

**Taxonomy.** *Picus superciliaris* Temminck, 1827, Cuba. Sometimes combined with other barred congeners in a separate genus *Centurus*. Forms a superspecies with *M. carolinus*. Birds on Grand Bahama sometimes separated as race *bahamensis*: on average marginally shorter-billed, slightly darker below and tending to show slightly more black behind eye, but otherwise identical to San Salvador race *nyeuanus*, which is itself somewhat variable, so the two are more appropriately lumped. Race *caymanensis* formerly considered a separate species. Five subspecies currently recognized.

**Subspecies and Distribution.**  
*M. s. nyeuanus* (Ridgway, 1886) - Grand Bahama and San Salvador (N & E Bahamas).  
*M. s. blakei* (Ridgway, 1886) - Great Abaco (N Bahamas).  
*M. s. superciliaris* (Temminck, 1827) - Cuba. Cantiles Keys and associated keys.  
*M. s. murceus* (Bangs, 1910) - I of Pines, Cayo Largo and Cayo Real.  
*M. s. caymanensis* (Cory, 1886) - Grand Cayman.

**Descriptive notes.** c. 27-32 cm; 83-126 g (*superciliaris*), 63-81 g (*caymanensis*). Male has red nasal tufts, white to buffish-white forehead and sides of forehead, red crown, nape and hindneck; narrow black area from just in front of eye backwards along side of mid-crown; pale grey to whitish head side, chin and throat, tinged buffy or yellow-brown; buffish-white upperparts (whiter when worn) barred black, rump with fewer and narrower bars, white uppertail-coverts with narrow black horseshoe markings; largely white wing-coverts narrowly barred black; black secondaries and tertials barred white, black primaries tipped white (when fresh)

and with white at bases forming patch; uppertail black, central feather pair with very broad white bars on inner webs and white at base of outer webs, outer pair barred white on outer webs; greyish below, breast strongly tinged buffy-brown, paler olive-yellow on lower breast, with central belly red to orange-red, flanks and undertail-coverts whitish with black arrowhead barring; underwing greyish, coverts barred black and white; undertail somewhat paler than above, greyish on outer tail; noticeably long bill only slightly chisel-tipped, culmen curved, fairly broad across nostrils, black; iris red-brown; legs olive-grey. Female is slightly (12%) shorter-billed, less bulky than male, has whitish forehead and crown, blackish rear crown joining black area behind eye. Juvenile similar to adult but less contrastingly patterned, often has red tinge above, larger but more diffuse red area below, both sexes with red crown, on female mixed with black feathering. Races differ mainly in size, also in plumage coloration and pattern: *murceus* resembles nominate, but averages smaller in bill, wing and, particularly, tail measurements; *nyeuanus* is much smaller than nominate, rather variable in plumage, has only small amount of black behind eye or none at all, markings on uppertail-covert more bar-like, underparts slightly greenish-tinged; *blakei* averages somewhat bigger and darker than previous, has pale bars above narrower and often tinged greenish-buff on mantle, generally greyer and darker face and underparts, less and paler red on nasal tufts, more black around and behind eye; *caymanensis* is size of previous or smaller, with shorter wing, has dark barring above much narrower, pale bars on back often strongly buffish, more evenly barred tail with white extending to outer webs of central rectrices, less regular uppertail-covert markings, no black around and behind eye, red of nasal tufts much paler and restricted, female with greyish (not black) hindcrown. **VOICE.** Typical "churr" call a loud "kruru", or repeated as "kruru-kruru-kruru-kruru", slightly higher-pitched than that of *M. carolinus*; also "waa" notes as *M. striatus*; also "key-out", and continuous "ke-ke-ke-ke" series.

**Habitat.** Various types of wooded area, especially dry forest, including edges; also coastal forest, palms, scrub, and edges of swampland; often around human habitations on Abaco and Grand Cayman. On Grand Cayman, occurs in all forest types, and is fairly common in mangrove forest, but possibly visits limestone forest only outside breeding season. Appears to favour open forest or bushy country with scattered royal palms (*Roystonea regia*) in Cuba, where probably partly excluded from many other habitats by competition from more aggressive *Xiphidiopicus percussus*. Sea-level to c. 900 m. **Food and Feeding.** Arthropods, including beetles, orthopterans, cockroaches (Blattodea) and others, and spiders. Occasionally small vertebrates taken, e.g. tree-frogs (*Hyla*) and geckos (*Sphaerodactylus*). Also fruit, including *Carica*, *Ficus*. In study on Grand Cayman, 56% of diet was insects, especially grasshoppers (Acrididae), and spiders, with the rest made up of fruit. Forages singly or in pairs. Forages at all levels, also descends to the ground. Pecks and probes in coarse bark on trunks or in dead branches, also in dry leaves at base of bromeliads; much of time spent in gleaning arthropods, and taking small fruits; shows great skill and agility in obtaining fruits at tips of small branches. On Grand Cayman, males foraged higher on trees and used pecking, while females more often hunted lower down by gleaning; fruit consumed in 38% of foraging time, with pecking recorded for 13% of time. Large items are broken in anvil before being swallowed or fed to chicks.

**Breeding.** Jan-Aug; possibly 2 broods. Nest excavated by both sexes, at 4-14 m, on average c. 7 m, in dead tree, live or dead palm (especially *Roystonea regia* in Cuba), or utility pole, occasionally in cactus; cavity depth 35-38 cm, mean size of entrance hole 8.8 cm high, 7.1 cm wide; territorial, radius of 20 m around hole defended. Clutch 2-6 eggs, usually 4-5; incubation period 12 days; fledging period not documented; both parents feed chicks, mean 13.5 deliveries per hour in one study; at another nest watched for 3-3 hours, male delivered 15 feeds and female 20, a rate of 1 feed every 5-6 minutes; young accompanied by parents for c. 10 days after leaving nest.

**Movements.** Resident. **Status and Conservation.** Not globally threatened. Common and widespread in Cuba and on I of Pines and offshore cays; common on Great Abaco; fairly common on Grand Cayman. Race *nyeuanus* is uncommon to scarce on San Salvador and probably extinct on Grand Bahama; surviving population considered to be threatened by continued loss of habitat. In most of range (but not islands occupied by *nyeuanus*), abandoned holes of this species are taken over by Cuban Amazon (*Amazona leucocephala*) for nesting.

54. Golden-fronted Woodpecker

*Melanerpes aurifrons*

**French:** Pic à front doré      **German:** Goldstirnspecht      **Spanish:** Carpintero Frentidorado  
**Other common names:** Gold-fronted Woodpecker

**Taxonomy.** *Picus Aurifrons* Wagler, 1829, Hidalgo, Mexico. Sometimes combined with other barred congeners in a separate genus *Centurus*. Forms a superspecies with *M. hoffmannii*, and sometimes regarded as conspecific. Hybridizes with later in S Honduras (R Pespire), with *M. carolinus* in S USA (Texas) and infrequently with *M. uropygialis* in SW Mexico. Geographical variation complex, and strong clinal variation in many plumage characters, making delimitation of races very difficult; in addition, mainland races, themselves variable to greater or lesser extent, intergrade, producing many populations with intermediate characters; *grateloupensis* possibly no more than an intergrade population. Subspecific treatment has varied greatly in the past, and some authors have recognized only 9 or fewer races; conversely, others have grouped races to form up to 4 separate species; further study needed. Paler birds from C Texas S to W Mexican Plateau described as race *incanescens*, but considered better merged with nominate; others from interior Chiapas described as race *frontalis*, tending towards nominate, but better treated as part of *polygrammus*. Twelve subspecies recognized.

**Subspecies and Distribution.**  
*M. a. aurifrons* (Wagler, 1829) - S USA from NW Texas and SW Oklahoma S across Mexican Plateau to Jalisco, NW San Luis Potosí and Hidalgo.  
*M. a. grateloupensis* (Lesson, 1839) - C San Luis Potosí and SW Tamaulipas to E Puebla and C Veracruz.  
*M. a. veraecrucis* Nelson, 1900 - Atlantic slope from S Veracruz to NE Guatemala.  
*M. a. dubius* (Cabot, 1844) - Yucatán Peninsula S to NE Guatemala and Belize.  
*M. a. polygrammus* (Cabanis, 1862) - Pacific slope from SW Oaxaca E through interior Chiapas.  
*M. a. santacruzii* (Bonaparte, 1838) - SE Chiapas E to El Salvador, SW Honduras and NC Nicaragua.  
*M. a. hughlandi* Dickerman, 1987 - upper R Negro and upper Motagua Valley in Guatemala.  
*M. a. pauper* (Ridgway, 1888) - coastal N Honduras.  
*M. a. leei* (Ridgway, 1885) - Cozumel I (off NE Yucatán Peninsula).  
*M. a. turneffensis* Russell, 1963 - Turneffe Is (off Belize).  
*M. a. insularis* (Bond, 1936) - Utila I (off N Honduras).  
*M. a. canescens* (Salvin, 1889) - Roatán I and Barbareta I (E of Utila).

**Descriptive notes.** c. 22–26 cm; male 73–99 g, female 63–90 g. Male of nominate race has yellow (rarely, orange-gold) nasal tufts, small red patch on centre of crown (very occasionally extending to nape), golden-orange (occasionally yellow) nape, becoming more orange-yellow on lower hindneck and often uppermost mantle; rest of head pale grey, darkest on hindcrown, palest on forehead and chin (rarely, faint yellowish wash); upperparts, including wing-coverts, evenly barred black and white, white rump and uppertail-coverts rarely with dark shaft streaks; flight-feathers black, secondaries and tertiaries barred white, outer primaries tipped white (when

fresh) and with white at bases forming patch; uppertail black, tipped white (when fresh), outermost feathers barred white on outer webs, sometimes also at tip of inner webs; entire underparts pale grey to whitish, central lower belly with narrow diffuse area of yellow (occasionally more golden-yellow), lower flanks and undertail-coverts barred blackish, often indistinctly on flanks; underwing greyish, coverts and inner wing barred, white primary patch; undertail often tinged buffish at sides; medium-long to long bill slightly chisel-tipped, culmen barely curved, fairly broad across nostrils, black to grey-black; iris deep red or red-brown, orbital skin grey to grey-brown; legs grey, usually tinged greenish. Differs from *M. hoffmannii* in larger size, more orange nape, somewhat paler underparts. Female is somewhat smaller than male, has pale grey crown without red (rarely, some red feathers), often yellower nape and hindneck than male. Juvenile duller than adult, markings less contrasting, dark bars above broader, dusky bars on forehead, streaked breast, paler belly patch, brown eyes, male with reddish crown patch smaller than adult's, female crown without red or with few scattered red tips (rarely, more red, almost as male) and nape and hindneck paler. Races differ from nominate mainly in head pattern, width of pale bars above, tail pattern, darkness of underparts, but very variable: *grateloupensis* is highly variable, some very like nominate, nasal tufts sometimes red, pale bars above tend to be rather narrow, male crown often all red; *veracruzensis* is rather small and dark, has red nasal tufts, nape and belly patch, pale bars above narrower, little or no white in tail; *dubius* as previous but longer-billed, pale bars above very narrow, underparts more grey-buff, red belly patch sometimes with diffuse golden border, white primary patch smaller, male with red crown to hindneck, female with nape and hindneck more orange-red; *polygrammus* has nasal tufts yellow or tinged orange, pale bars above broader than on previous, underparts somewhat paler, belly patch golden-yellow, central rectrices barred white on inner webs, male with orange-red crown grading into yellower nape and hindneck (sometimes broken at upper nape), female with whitish to grey crown and nape, orange-yellow hindneck; *santacruzensis* has short bill, short tail, nasal tufts yellow or yellow-orange, pale bars above tinged yellow-brown in fresh plumage, central rectrices usually with some white, rather dark buff-grey below, belly patch more golden-orange or orange-yellow, male with entire crown red, nape orange-red, female generally with pale upper nape; *hughlandi* resembles previous, but longer-winged, has pale bars above broader, no yellow wash; *pauper* is like previous, but much shorter-winged, pale bars above normally very narrow; *leei* is long-billed, long-tailed, dark, has red nasal tufts, pale bars above very narrow and brown-tinged, white rump and tail-coverts dark-barred, little or no white in tail, brownish below, dark red belly patch, male with entire crown to hindneck red, sometimes meeting red of nasal tufts; *turneffensis* resembles previous, but red colours more orangey, pale bars above slightly broader, underparts paler; *insulanus* is rather large, long-tailed, has yellow-orange nasal tufts, white supercilium, little or no white in tail, male crown all red, hindneck orange-red; *canescens* has very long bill, red nasal tufts, hindneck and belly, very pale face and underparts, pale bars above fairly narrow, white spots on inner primaries, male crown all red. Voice. Tremulous rolling "pwurr-r-r-r", slightly shorter and higher than that of *M. carolinus*, as contact and advertisement, also "kek-kek-kek-kek" as warning, and other nasal and rolled calls; repertoire as for *M. carolinus*, but calls generally louder, harsher. Drumming occasional, almost always by male, series of single short rolls preceded or followed by 1–4 taps; mutual tapping.

**Habitat.** Typically, arid or semi-arid country with sparse to tall second-growth woodland; also mesic areas. In USA, xeric vegetation dominated by mesquite (*Prosopis*), also riparian cottonwood (*Populus*), mixed oak (*Quercus*) woodland, and juniper (*Juniperus*) country, also in pecan (*Carya*) groves and in open areas on floodplains; small numbers in areas of live oaks (*Q. fusiformis*), elms (*Ulmus*) and other mesic types in residential districts, especially where adjacent to stands of mesquite, deciduous oak and/or juniper. Enters suburban areas and urban parks. In Mexico and Central America, also arid tropical scrub with paloverde (*Cercidium praecox*), mesquite and cacti, and short-tree tropical deciduous forest with dense thorny understorey; also tropical evergreen forest with open canopy in SE. From sea-level to 2500 m.

**Food and Feeding.** Rather catholic in diet. Wide variety of insects and their larvae, including those of wood-boring beetles, ants, and grasshoppers, Lepidoptera, Homoptera, mantids, phasmids; also spiders; possibly also bird eggs, and once seen to kill lizard (*Sceloporus*). Consumes large amounts of fruits, berries, nuts (e.g. pecan) and various seeds, particularly acorns and corn, also mesquite. Visits feeders. Hunts singly or in pairs, sometimes in family groups; occasionally joins mixed-species flocks on ground. Most foraging is on medium-sized to large branches and on trunks. Gleaning and searching (50%), pecking and hammering (28%), and probing in crevices and holes (13%) constitute most important feeding techniques; also some flycatching, ground-feeding, and picking of fruits. Slight sexual differences in foraging behaviour recorded in Texas: in autumn males pecked more and gleaned less than females, which resorted more to ground-feeding; in late winter, however, males pecked less frequently than females and fed more on ground, visiting small twigs rarely. Occasionally stores food (seeds, nuts, fruits) in crevices and holes in early winter. Attacks other bird species at fruit trees or near seed stores.

**Breeding.** Late Mar to Jul in Texas, from Jan in S Mexico (Chiapas), and Feb–Aug in Guatemala; sometimes 2 broods, in Central America even rarely 3. Monogamous; solitary. Nest excavated by both sexes, completed in less than 2 weeks, at 2–9 m, sometimes lower or higher, in large branch or trunk or live or dead tree, or often at top of telephone pole, or in fence post, mean cavity depth 31.6 cm, and entrance hole 5.5 cm high, 4.9 cm wide; nest-hole often reused; nestbox, or male's roost-hole occasionally used; territory large, 14.4–23.3 ha in WC Texas. Clutch 4–5 eggs, occasionally up to 7, average 4.75, clutch size increasing somewhat with latitude; incubation by both parents, only male during the night, period 12–14 days; both also brood and feed chicks, deliver insects and berries carried in bill; fledging period c. 30 days; juveniles accompanied by parents for several weeks, sometimes until autumn. Annual success in WC Texas 1–4 young per successful pair; nests sometimes preyed on by rat snakes (*Elaphe*). First breeding at 1 year. Recorded longevity 5 years 8 months.

**Movements.** Resident; occasionally wanders N, E or W of normal range.

**Status and Conservation.** Not globally threatened. Common to fairly common throughout its range, locally very common. Local abundance varies annually; breeding surveys in a study area in S Texas found 3.65 territories/ha during 1973 to 1978 but 1.04 territories/ha in 1994 to 1996. Expanded N and W in 20th century; first recorded in Oklahoma in 1954. Population size and range in large parts of Texas and Oklahoma appear to have increased since 1960; species has benefited from proliferation of mesquite on rangeland. Was formerly persecuted in S USA for its habit of nesting in utility poles and fence posts, as a result of which it suffered significant decline during 1930–1950; current levels of persecution considered minimal, and unlikely to have adverse effect on total population. Habitat alteration, especially removal of mesquite in S USA brushlands, can reduce availability of nesting and foraging sites. Nevertheless, this woodpecker seems adaptable, able to flourish in human-altered environments, and has successfully colonized urban parks. No real threats known.

## 55. Hoffmann's Woodpecker

### *Melanerpes hoffmannii*

French: Pic de Hoffmann German: Hoffmannspecht Spanish: Carpintero de Hoffmann

**Taxonomy.** *Centurus Hoffmannii* Cabanis, 1862, Costa Rica.

Sometimes combined with other barred congeners in a separate genus *Centurus*. Forms a superspecies with *M. aurifrons*, and sometimes regarded as conspecific. Hybridizes with latter in S Honduras (R Pespire) and with *M. rubricapillus* in C Costa Rica, producing numerous individuals with intermediate appearance (e.g. majority between Tárcoles and Quepos, in Costa Rica, have orange hindneck and belly). Monotypic.

**Distribution.** Pacific slope from S Honduras and Nicaragua S to Costa Rica (S to Quepos, and on Caribbean slope to Turrialba).

**Descriptive notes.** c. 19–21 cm; 62–84 g. Male has pale golden-yellow nasal tufts, red crown patch, golden-yellow to orange-yellow nape and hindneck sometimes with few scattered red tips, becoming paler on uppermost mantle; rest of head very pale grey-buff to brownish-grey, this colour frequently continuing over hindcrown, whiter at front of face, often pale yellow feather tips in loreal area; black upperparts barred white, white rump and uppertail-coverts occasionally with few black spots or bars; black wing-coverts usually with fewer white bars than back, broad on greater; secondaries and tertiaries similarly barred, white bars broad-

on tertials; black primaries tipped white (when fresh), outer feathers broadly barred white at base of inner webs, may form small patch; uppertail black, central feather pair white on inner webs with black half-bars, outer webs with white at base, outermost pair narrowly barred white on outer webs; pale greyish below, breast slightly olive-tinged, central belly diffusely golden-orange or orange-gold, flanks and undertail-coverts often yellow-washed, ventral region with blackish arrow-head bars; underwing dark brownish, barred white; undertail as above, sides brownier; fairly long bill minimally chisel-tipped, culmen slightly curved, rather broad across nostrils, black; iris red or red-brown, orbital skin brownish; legs grey. Female is slightly smaller, shorter-billed than male, nasal tufts often paler, lacks red on head, having crown and nape pale. Juvenile duller and darker, has barring above less sharp, underparts more olive, belly patch paler, lower underparts (and sometimes breast) mottled dark, eyes brown, head pattern as respective adult, female occasionally with trace of red on crown. Voice. Most common are loud to soft "churr" calls, like those of *M. aurifrons*; hard metallic rattle in short bursts; prolonged nasal rattle or splutter, wavering in pitch; querulous, grating "woick-a-woick-a-woick-a" or "wit wit wit" in excitement. Also drums.

**Habitat.** Xeric to mesic open and semi-open country. Typically, deciduous forest, light woodland, second growth, shade trees in coffee plantations, gardens, also scattered trees in pastures; often near human habitation. Avoids dense wet forest, but may invade when forest cut. Occurs from sea-level up to 200 m in Honduras; mostly at 600–2150 m in Costa Rica, though also occurs at lower altitudes in N.

**Food and Feeding.** Insects, particularly ants, beetles, lepidopterans, and their larvae. Eats many fruits, including figs (*Ficus*), also *Cecropia* catkins, and arils. Takes nectar of balsa (*Ochroma*), African tulip tree (*Spathodea*), and other large flowers. Forages singly or in pairs. Largely arboreal, but often descends to low level on stumps and posts. Pecks and hammers wood, flakes off pieces of bark, probes; clings head downward to obtain berries, reaching with stretched neck.

**Breeding.** Feb–Jul; often 2 broods. Monogamous, in pairs throughout year; solitary nester. Often conspicuous encounters between pairs before breeding season; displays include bobbing entire body, with calling and wing-spreading. Nest-hole 1.5–5.9 m up in dead trunk or branch, sometimes only 1 m up in fence post. Clutch 2–3 eggs; incubation and fledging periods not documented, probably similar to *M. aurifrons*. Frequently mobs pygmy-owls (*Glucidium*), indicating possible hole competition or nest predation by latter.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common in N of range; common to locally very common in Costa Rica. Occurs in Santa Rosa, Palo Verde and Barra Honda National Parks (Costa Rica). Adaptable, able to utilize human-altered habitats. Has expanded its range in Costa Rica since 1960; as it prefers open and semi-open terrain with scattered trees, it benefits from clearance or thinning of forest. No known threats.

## PLATE 28

## Family PICIDAE (WOODPECKERS) SPECIES ACCOUNTS

### Genus *SPHYRAPICUS* Baird, 1858

#### 56. Yellow-bellied Sapsucker

##### *Sphyrapicus varius*

French: Pic maculé German: Gelbbauch-Saftlecker

Spanish: Chupasavia Norteño

Other common names: Common Sapsucker

**Taxonomy.** *Picus varius* Linnaeus, 1766, North America = South Carolina.

Forms a superspecies with *S. nuchalis* and *S. ruber*; sometimes treated as conspecific with former, and in past also with latter; hybridizes to limited extent with former in SW Canada (Alberta), more rarely with latter where ranges overlap. Birds from S Appalachian Mountains sometimes separated as race *appalachiensis* on basis of slightly darker plumage and marginally smaller size, but considerable overlap with N populations; subspecific recognition considered unwarranted. Monotypic.

**Distribution.** S Yukon, SW Northwest Territories and NE British Columbia E to NC Ontario, S Labrador and Newfoundland, and S to C Alberta, E South Dakota, N Iowa and Appalachians (S to SW North Carolina). Winters SE USA (S from about S Kansas, S Ohio and Connecticut) S to Panama.

**Descriptive notes.** c. 19-21 cm; 41-62 g, mean 50.3 g. Male has bright red (exceptionally, yellow) forehead and crown bordered black, broader black across hindcrown, white stripe from above eye broadening to rear and nape (nape rarely with trace of red) and down hindneck side, narrow black band down hindneck, broad black band through ear-coverts and down neck side bordered below by white stripe from nasal tufts to neck side and down to breast side; red chin and throat bordered

black; white mantle to rump with heavy, irregular black bars, black outer scapulars, white lower rump and uppertail-coverts with black outer webs; black wing-coverts with large white panel on medians and central greater; black flight-feathers tipped white, white spots on both webs forming bar-like pattern, innermost tertials white with black bars; uppertail black, central feather pair with white inner webs (few black bars or spots) and sometimes some white at tips of outer webs, outer 2 or 3 pairs often with white marks near tips, outermost also with thin white edge on outer web; underparts below breast pale yellow, whiter in lower region, breast side to lateral undertail-coverts with narrow blackish arrowheads and usually shaft streaks; underwing barred greyish and white, coverts mostly dusky; in fresh autumn plumage, white parts tinged yellow or buffish, black breast patch and markings below partly obscured by broad yellowish fringes; relatively short bill straight, chisel-tipped, broad across nostrils, slaty-grey to blackish; iris deep brown; legs blue-grey to green-grey. Distinguished from extremely similar *S. nuchalis* by lack of red nape patch, less red on throat, more white in wings; from *S. ruber* by patterns of head and breast. Female differs from male in having white chin and throat, usually paler red forehead and crown sometimes mixed with black, or red restricted to patches on forehead, or occasionally top of head all black or with few buff spots. Juvenile very different, mainly dark olive-brown, head striped buff, crown streaked, above barred and mottled blackish and pale, throat whitish, breast scaly, central belly pale yellowish-white, tail more extensively barred, male sometimes with some red on throat; protracted moult to adult plumage, not completed until spring. Voice.

Nasal, cat-like, single or grouped squeals, "neeah", "owee-owee", "wee-wee-wee-wee" or "kwee-

urk", at start of breeding, as long-distance signal; soft mew in alarm, louder and hoarser with increasing excitement; "weetik-weetik" calls in aggression; "juk-juk-juk" during encounters; soft "mjuk" notes, e.g. when pair-members meet at nest; incessant chatter by nestlings. Drumrolls very distinctive with well-separated taps at end, sometimes also at beginning, "tap-tap-trrrrrrrr-ta-tat-tat—tat", by both sexes; ritual tapping at lower rim of nest-hole.

**Habitat.** When breeding, inhabits deciduous and mixed coniferous forests; presence of aspen (*Populus*) important for nesting, birch (*Betula*) and hickory (*Carya*) also important tree species in habitat; generally up to c. 2000 m. In winter, mostly forest, including montane forest, but usually not pure conifer stands; also forest edge, open woodland and semi-open habitats; visits larger trees in pastures, clearings and suburban areas; occasionally found in coastal palm groves; in wintering zones occurs from sea-level up to c. 3200 m, locally up to 3500 m, but mainly 900–3000 m.

**Food and Feeding.** Arthropods, especially beetles and their larvae, ants and their brood, also Lepidoptera, and dragonflies (Odonata); also large quantities of tree sap; fruit and nuts also taken, and in spring buds. Berries occasionally taken, even fed to nestlings in times of food shortage. Insects comprise almost half of diet during nesting season; sap and phloem make up main food in late summer and autumn, and important also at other times; fruits taken mostly in Oct–Feb. Observed to place fruits, nuts or acorns in crevices, but uncertain whether this behaviour involves anvil use or food-storing. Forages singly; sometimes small groups on migration; will join mixed flocks of insectivores in winter. In spring, prefers to forage on live branches in lower canopy; descends to ground to take carpenter ants (*Crematogaster*). Digs in dead or dying wood, flakes off bark to expose ants and their brood. Hangs on outermost tips of twigs when reaching for buds. Flycatching also important at times; sallies from exposed perch, returning to the same or another perch. Sap and phloem are sought at all levels, on trunk as well as in crown of trees. Numerous tree species utilized, both deciduous (especially *Populus*, *Salix*, *Betula*, *Acer*, *Carya*, *Alnus*) and coniferous (mainly *Pinus*, *Picea*, *Abies*); in N Michigan preferentially selected paper birch (*Betula papyrifera*), red maple (*Acer rubrum*), juneberry (*Amelanchier*) and bigtooth aspen (*Populus grandidentata*). In late summer and autumn, drills shallow holes arranged in vertical columns, in horizontal bands, or on twigs in spiralling bands; in spring, uses old sap wells or other sources of sap on bruised parts of trees. Sap wells exploited by a wide variety of other birds, as well as numerous insects and mammals.

**Breeding.** Apr–Jul. Monogamous; solitary. Nest excavated mostly by male, taking c. 15–28 days, some further excavation by both sexes after chicks hatch; at 2–20 m, mostly 3–14 m, in live tree, especially *Populus* or *Betula*, usually one with rotten heartwood; nest-hole very occasionally re-used; territorial. Flutter-aerial displays, also perched displays with bill-pointing, wing-spreading, bobbing. Clutch 4–7 eggs, average 4.93, clutch size increases from S to N; incubation by both sexes, period 12–13 days; both also take about equal share in feeding chicks, male carries out most of the nest sanitation; young leave nest after 25–29 days, fully independent after c. 2 weeks. Nest preyed on by snakes. First breeding at 1 year.

**Movements.** Migratory, winters well S of breeding range. Leaves breeding areas from late Aug, sometimes not until Oct–Nov; a few may remain in N parts. Winter range from S & SE USA to Central America (S to Costa Rica, more rarely to W Panama), including all of West Indies; in Mexico mainly E & S from E Chihuahua and S Sinaloa. Females migrate farther S than males. N migration from Mar, arrival at breeding grounds from late Apr to May; males return earlier than females. Most passage is through C & E parts of North America, but numerous records also from W; vagrants recorded in Netherlands Antilles, and three times in British Is.

**Status and Conservation.** Not globally threatened. Fairly common to common throughout range; reasonably common, but often inconspicuous, on non-breeding grounds. Has disappeared from some former breeding grounds in south of range; precise reasons uncertain. No known threats, but fairly specific habitat requirements, including presence of suitable trees for sap-feeding, need to be borne in mind; preservation of older large trees for nesting important. Within the ecosystem, plays an important role in providing other organisms with a rich resource in the form of sap.

## 57. Red-naped Sapsucker

### *Sphyrapicus nuchalis*

**French:** Pic à nuque rouge **German:** Rotnacken-Saftlecker **Spanish:** Chupasavia Nuquirrojo

**Taxonomy.** *Sphyrapicus varius* var. *nuchalis* Baird, 1858, southern Rocky Mountains = Mimbres River, New Mexico, USA.

Forms a superspecies with *S. varius* and *S. ruber*; sometimes treated as conspecific with former, and in past also with latter; hybridizes occasionally with former in SW Canada (Alberta), more frequently with latter in various areas; has interbred rarely with *S. thyroideus*. Monotypic.

**Distribution.** Rocky Mountains from SE British Columbia and SW & SE Alberta E to W South Dakota, and S, discontinuously, to SE California, E Arizona and NE & S New Mexico; in winter from S California, Arizona and W Texas S to SC Mexico.

**Descriptive notes.** c. 19–21 cm; 36–61 g, mean 52.4 g. Male has bright red forehead and crown, black band on hindcrown, red nape, black band down hindneck, narrow white stripe from eye to nape side and down hindneck side, black band from eye through ear-coverts (sometimes dull red) to neck side, white stripe from nasal tufts back to neck side and down to breast side; red chin, throat and malar, black band below; black upperparts, broad row of white bars each side of mantle and back (white less obvious in worn summer plumage), white lower rump to uppertail-coverts, white panel on wing-coverts; black flight-feathers tipped white, variably barred white; uppertail black, central feather pair with white inner webs barred black, outer pair with thin white edge on outer web; underparts below breast pale yellow, belly to vent whiter, blackish arrowheads and usually shaft streaks from breast side to lateral undertail-coverts; underwing barred greyish and white; in fresh autumn plumage, white parts tinged yellow or buffish, black breast patch and markings below

barred; more as adult by autumn (from Oct), but not fully so until Jan. Voice: Mewing "meeah", lower-pitched than that of *S. varius*, also more vibrant shorter versions in flight; squealing series, mainly by male in early breeding season, individual notes shorter and delivered at faster rate than by *S. thyroideus*; low calls during change-over at nest. Drumroll as initial burst, followed by irregular slower burst of 2–3 strokes, 8–9 rolls per minute, by both sexes.

**Habitat.** Deciduous forest containing aspen (*Populus tremuloides*), or in pure aspen stands; also coniferous forest, e.g. with Douglas fir (*Pseudotsuga menziesii*), larch (*Larix*), spruce (*Picea*) or fir (*Abies*), particularly if aspen present; in montane habitats to 2900 m. Where sympatric with *S. thyroideus* in Colorado, favours areas near deciduous or mixed coniferous forest, whereas latter prefers sites adjoining open ponderosa pine (*Pinus ponderosa*) forest. Non-breeding habitats include forest and forest edge, also mixed oak (*Quercus*) and juniper (*Juniperus*) woodland, mixed pine-oak and pure oak woodland, in mountains to 1700 m; in Mexican winter quarters from sea-level to 2500 m.

**Food and Feeding.** Arthropods, tree sap; diet presumably similar to that of *S. varius*. Ants (*Camponotus*) apparently important as nestling food. Relies greatly on conifer sap during spring. Forages singly, sometimes small groups on migration. In spring mostly in lower canopy, where excavates in dead wood, flakes off bark. Sap holes used throughout year; exploits various conifers and deciduous trees and bushes on breeding grounds; oaks preferred in winter quarters.

**Breeding.** May–Aug. Monogamous, male and female may reunite in consecutive seasons; solitary. Nest excavated at 1–25 m in tree, e.g. aspen, paper birch (*Betula papyrifera*) or larch, preferably with some dead parts; several holes may be initiated, and one started in previous season is often selected, but old holes also reused; territorial, attacks *S. thyroideus* and other picids, e.g. *Picoides villosus*, in vicinity of nest. Clutch 3–7 eggs, usually 4–6; incubation by both sexes, period c. 13 days; nestlings fed by both parents, male takes greater share in nest sanitation; female helper once observed feeding nestlings of hybrid pair; fledging period 25–28 days; young quickly become independent, both they and adults soon leave nest area. Productivity 1–6 young reared per nest, mean c. 3 chicks fledging.

**Movements.** Migratory. Leaves breeding areas mostly in Sept, moving relatively short distances. Winter range from S Nevada, Arizona, SW New Mexico and W Texas S to S Baja California and NW Mexico (E to SW Nuevo León, S to Jalisco); some individuals occasionally reach Guatemala and Honduras. Females tend to migrate farther than males. Return passage from Mar, often not until Apr, arrival on breeding grounds Apr–May. Recorded on passage in W California, and F to Louisiana.

**Status and Conservation.** Not globally threatened. Fairly common in breeding range; fairly common in Mexican non-breeding range; few data. No known threats; protection and appropriate management of its habitats would appear to be sufficient to secure its future. At least locally important as a provider of holes for other birds; in 3019 ha of forest reserve in NW Montana, all nests of Mountain Chickadee (*Parus gambeli*) and almost 50% of Red-breasted Nuthatch (*Sitta canadensis*) nests were found in old holes made by this species.

**Bibliography.** Anon. (1998b), Baicich & Harrison (1997), Bent (1939), Bock & Larson (1986), Campbell *et al.* (1990), Cicero & Johnson (1994, 1995), Crockett & Hadow (1975), Daily (1993), DeGraaf & Rappole (1995), Ehrlich & Daily (1988), Hadow (1977), Howell, S.N.G. & Webb (1995), Howell, T.R. (1952), Johnson & Johnson (1985), Johnson & Zink (1983), Kaufman (1996), Keisker (1986), Koenig (1986, 1987), Lockwood & Shackelford (1998), Mayr & Short (1970), McClelland & McClelland (2000), Price *et al.* (1995), Rojas *et al.* (2001), Saab & Dudley (1998), Schepps *et al.* (1999), Scott *et al.* (1976), Short (1969a), Short & Morony (1970), Small, A. (1994), Small, B. (2000), Smith (1982), Tobalske (1992, 1996), Trombino (1998, 2000), Weisser (1973), Wiedenfeld *et al.* (1992).

## 58. Red-breasted Sapsucker

### *Sphyrapicus ruber*

**French:** Pic à poitrine rouge **German:** Feuerkopf-Saftlecker **Spanish:** Chupasavia Pechirrojo

**Taxonomy.** *Picus ruber* J. F. Gmelin, 1788, Cayenne; error = Nootka Sound, British Columbia, Canada.

Forms a superspecies with *S. varius* and *S. nuchalis*, and in the past sometimes treated as conspecific; hybridizes with both, but especially latter, wherever ranges overlap. Races intergrade, fully so in extreme S Oregon. Two subspecies recognized.

**Subspecies and Distribution.**

*S. r. ruber* (J. F. Gmelin, 1788) - S Alaska S to W Oregon.

*S. r. daggetti* Grinnell, 1901 - SW Oregon N & E California and W Nevada.

lowish-white belly, white lower ventral region, irregular arrowhead markings most prominent on

flanks; underwing barred grey and white, coverts more uniform; shortish bill straight, chisel-tipped, broad across nostrils, black; iris deep brown; legs grey to green-grey. Juvenile has similar pattern, but different colours: red replaced by dark brown with red wash, rump barred, underparts grey-brown and extensively barred except central belly; identical to adult by late summer or early autumn. Race *daggetti* marginally smaller, red duller, has white of lores continuing as moustachial stripe of variable length, pale markings above whiter and more like bars, red on breast less extensive, belly paler. VOICE. Mewing, rather drawn-out "meeah", quiet "puc" or "pwuc" notes, also other call types; voice much as that of *S. varius*. Drumroll as initial burst, followed by irregular, slower burst of 2-3 strokes, by both sexes.

**Habitat.** Mixed deciduous and coniferous forest and forest edge, particularly associations of aspen (*Populus tremuloides*) and ponderosa pine (*Pinus ponderosa*); coastal populations inhabit humid forest dominated by conifers. At up to 2900 m during breeding season; 500-3000 m in winter quarters.

**Food and Feeding.** Arthropods and sap; presumably, nuts and fruits also taken. Insects, especially ants, comprise an important nestling food. Diet and foraging habits similar to those of *S. varius* and *S. nuchalis*. Forages singly, sometimes in small groups; may join *S. thyroideus* on migration. Mostly in lower canopy; excavates in dead wood, flakes off bark. Sap holes apparently utilized throughout year.

**Breeding.** Apr-Jul. Monogamous; solitary. Nest usually high up in tree, conifer apparently preferred. Clutch 4-7 eggs; incubation 14-15 days; both parents feed chicks, possibly exceptionally with 1 helper; also, male *S. thyroideus* once seen helping pair of present species, fed nestlings less frequently than did parents; fledging period probably c. 28-30 days.

**Movements.** Resident and short-distance migrant. Less migratory than congeners; nominate race more or less sedentary, or withdraws only short distance from extreme N parts. In non-breeding season occurs S to N Baja California, sometimes slightly farther S to about 29°N. Remains in winter quarters Oct-Mar, return to breeding grounds beginning Apr. Occasional migrants recorded W to C Texas.

**Status and Conservation.** Not globally threatened. Reasonably common throughout most of its range; race *daggetti* fairly common in Sierra Nevada; no detailed information on numbers. Outside breeding season, uncommon to rare in Baja California but possibly overlooked. No obvious threats.

**Bibliography.** Anon. (1998b), Baicich & Harrison (1997), Bent (1939), Campbell *et al.* (1990), Cicero & Johnson (1994, 1995), Howell, S.N.G. & Webb (1995), Howell, T.R. (1952), Johnson, E.V. (2000), Johnson, N.K. & Johnson (1985), Johnson, N.K. & Zink (1983), Kaufman (1996), Koenig (1986, 1987), Lockwood & Shackerford (1998), Mayr & Short (1970), Price *et al.* (1995), Scott *et al.* (1976), Short (1969a), Short & Morony (1970), Shuford (1985), Small, A. (1994), Small, B. (2000), Stark *et al.* (1998), Stevenon *et al.* (1998), Trombino (1998, 2000), Weisser (1973), Wiedenfeld *et al.* (1992).

## 59. Williamson's Sapsucker

### *Sphyrapicus thyroideus*

French: Pic de Williamson      German: Kiefersaftflecker      Spanish: Chupasavia Oscuro

**Taxonomy.** *Picus thyroideus* Cassin, 1851, Georgetown, Eldorado County, California, USA.

Has hybridized rarely with *S. nuchalis*. Two subspecies recognized.

#### Subspecies and Distribution.

*S. t. thyroideus* (Cassin, 1851) - S British Columbia S through Cascade Range and Sierra Nevada to N Baja California (San Pedro Mártir Mts).

*S. t. nataliae* (Malherbe, 1854) - SE British Columbia S through Rockies to Arizona and New Mexico; winters in S of range and S to SC Mexico.

**Descriptive notes.** c. 21-23 cm; 44-64 g. Male has white nasal tufts, lores and long moustachial stripe, white stripe from above eye curving down on nape side, red chin and upper throat; rest of head and neck, breast and most of upperparts glossy blue-black, gloss strongest on head, mantle and scapulars; white rump and uppertail-coverts with black on outer webs of feathers; large white panel across median and greater wing-coverts; black flight-feathers, small white spots on inner webs of primaries and secondaries, primaries also small white spots on outer webs, tertials narrowly tipped white; uppertail black, sometimes a few white

bars or streaks on central feathers; bright yellow lower breast to lower belly, white breast sides down to undertail-coverts with broad black streaks or arrowheads; underwing barred dark grey and white, coverts more uniform; shortish bill straight, chisel-tipped, broad across nostrils, black; iris deep brown to dark chestnut; legs grey. Female very different, head rather variable, brownish to buffish, usually streaked darker, buff moustachial area, dark-streaked or blackish submoustachial, generally yellowish-brown throat centre, sometimes buff with blackish chin (rarely, very small area of red), upperparts barred black-brown and buff to white, white rump and uppertail-coverts, dark brown wings barred buff to white, brownish-black tail barred buff-white on central and outer feathers; barred black and buff to white below, breast often solidly black (especially when worn), pale yellow lower breast to lower belly unmarked, some have brighter yellow belly, more solid black on breast, more streaked pattern at sides. Juvenile male like adult but duller, no gloss, has more barring on wings and tail, often a few small white spots on upperparts, generally some white on hindneck and nape sides often meeting to form pale patch, also white throat, paler yellow belly; juvenile female like adult but duller, browner, more heavily barred, head and throat often streaked or barred, fully barred breast (no impression of black patch), unmarked area of belly smaller and paler yellow to whitish; both sexes much as adult by early autumn. Race *nataliae* has longer, broader, deeper bill. VOICE. Single explosive, pulsating calls distinctive; also low-pitched guttural "k-k"-r-r-r"; squealing series, slower with shorter elements than *S. nuchalis*; low, nasal calls in close encounters between pair-members; whinnying chorus by nestlings when fed, also constant chattering in nest. Drumming distinctive, roll begins with a burst, followed by several rhythmic groups of 2-4 strokes that are slower than in congeners, c. 5 rolls per minute.

**Habitat.** Mixed montane forest dominated by spruce (*Picea*), firs (*Abies*) and pines (*Pinus*); also mixed stands of aspen (*Populus tremuloides*) and fir. Typical trees in habitat are ponderosa pine (*Pinus ponderosa*) and Douglas fir (*Pseudotsuga menziesii*), also larch (*Larix*), other pines. Prefers bottom of drainages rather than slopes and ridges. Breeds at 1500-3200 m, in extreme N at 850-1300 m. In Colorado, found at sites adjoining open ponderosa pine forest, while *S. nuchalis* more in areas near deciduous or mixed coniferous forest. Winters in humid to mesic habitats, especially mixed pine and oak (*Quercus*) and mixed oak-juniper (*Juniperus*) woodland, at up to 1830 m in

Arizona and at 1000-3500 m in Mexico. Observed also in various lower-lying habitats, including scrub and desert, on migration.

**Food and Feeding.** Diet consists of insects, including ants, beetles, larvae, dipterans, Homoptera; also sap; nestlings fed mostly wood ants (*Formica*) and carpenter ants (*Crematogaster*). In non-breeding season tree sap and phloem, also many fruits, and berries; in S Arizona, wintering females took large quantities of madrone (*Arbutus*) berries. Forages singly, on migration in small groups. Hunts from crown down to low levels. Insects taken mostly by gleaning, but other techniques used are bark-scaling, probing and pecking; also hawks aerial insects. Some sexual differences apparent: females forage more on oaks, and on trunks; males prefer pines, and glean more on limbs and on the ground. Sap taken from various tree species, including lodgepole pine (*Pinus contorta*), alpine hemlock (*Tsuga*), red fir (*Abies magnifica*), white fir (*A. concolor*), Jeffrey pine (*P. jeffreyi*) and aspen.

**Breeding.** Mid-Apr to Jul; peak of laying in first week Jun. Monogamous; solitary. Nest-hole drilled at 0.8-26 m in snag, or in live tree with rotten core, most commonly quaking aspen, also conifer (e.g. larch), exceptionally in utility pole; mean depth of cavity c. 27 cm; territory 4-9 ha, inter-nest distance 175-375 m. Flutter-aerial displays, particularly when approaching mate on the wing, also perched displays with bill-pointing, swinging, bobbing. Clutch 3-7 eggs, most commonly 4-6; both sexes incubate, only male at night, period 12-14 days; chicks fed and brooded by both parents, also fed sometimes by unmated males but these chased off; male carries out most of nest sanitation; initial feeding rate low, rises to 1 feed every 3 minutes in third week, drops again 3-4 days prior to fledging; nestling period 31-32 days; young fed by parents for further 1-2 days, siblings may remain together for 1-3 weeks. Number of nests producing at least 1 fledgling 89.4% to 100% in Arizona; nests preyed on by squirrels (*Tamiasciurus*), weasels (*Mustela*) and snakes. First breeding at 1 year.

**Movements.** Largely resident; but some migratory movements, and also post-breeding dispersal to lower elevations. Leaves British Columbia in early Sept, some not until mid-Oct; E race *nataliae* more migratory than nominate, moves S to N Mexico, some to as far as Jalisco and Michoacán, in flocks of up to c. 12 individuals; females probably migrate farther S than males. Return passage from Mar or earlier; arrival on breeding grounds mid-Mar to Apr in Oregon, mid-Apr in British Columbia, from early Apr in Colorado; males earlier than females. Casual records E of range, E to Minnesota, Illinois, Louisiana, mostly in spring.

**Status and Conservation.** Not globally threatened. Fairly common in USA; fairly common breeder in N Baja California. No information on total numbers; density 1 pair/40 ha in California, 4-1 pairs/40 ha in N Colorado, 1 pair/17 ha in S Colorado. Has decreased in USA since early 1980's; 60% decline reported in Pacific Northwest between 1984 to 1993. Locally considered a sensitive species, with rather specialized habitat requirements; needs relatively soft trees for excavation. Tolerant of habitat disturbance, but requires high density of dead wood. Preservation of groups of large dead trees, as well as of large sap trees (conifers), important for this species' survival.

**Bibliography.** Baicich & Harrison (1997), Baldwin (1960), Bent (1939), Bock & Larson (1986), Bull (1981), Campbell *et al.* (1990), Cicero & Johnson (1994), Conway & Martin (1993), Crockett (1975), Crockett & Hadow (1975), Crockett & Hansley (1977), DeGraaf & Rappole (1995), Dobbs *et al.* (1997), Hadow (1977), Howell & Webb (1995), Hutto (1992, 1998), Johnson & Zink (1983), Kaufman (1996), Koenig (1986, 1987), Kratter (1991), Michael (1935), Piel (1993), Price *et al.* (1995), Raitt (1959), Remsen (1991), Root (1988), Russell (1947), Schepps *et al.* (1999), Short & Morony (1970), Small (1994), Smith (1982), Sousa (1983b), Stallcup (1968), Stark *et al.* (1998), Swarth (1917), Trombino (2000), Wilbur (1987), Wilson & Rea (1976), Zusi & Marshall (1970).

## Genus XIPHIDIOPICUS Bonaparte, 1854

## 60. Cuban Green Woodpecker

### *Xiphidiopicus percussus*

French: Pic poignardé      German: Blutfleckspecht      Spanish: Carpintero Tajá  
Other common names: Cuban Woodpecker

**Taxonomy.** *Picus percussus* Temminck, 1826, Cuba.

Distinctive, with no very close relatives. Four additional races have been named, but species exhibits considerable variation in size and coloration throughout range, and much overlap in characters among different populations; thus, described races *monticola* (E Cuba) and *cocoensis* (Cayo Coco and nearby cays) are regarded as synonyms of nominate race, and *gloriae* (Cantiles Keys) and *marthae* (Cayo Caballones) as synonyms of *insulaepinorum*. Two subspecies currently recognized.

#### Subspecies and Distribution.

*X. p. percussus* (Temminck, 1826) - Cuba, including archipelagos of Sabana and Camagüey.

*X. p. insulaepinorum* Bangs, 1910 - I of Pines, Cantiles Keys and Archipiélago Jardines de la Reina (Cayo Caballones).

**Descriptive notes.** c. 21-25 cm; 48-97 g, male c. 20% heavier than female. Male has red crown to nape, short crest and hindneck, some black feather bases usually visible (especially on forehead), blackish stripe from behind eye and down rear neck side; white forehead and rest of face; black chin; feathers of throat and centre of upper breast broadly tipped red, forming red patch; green upperparts variably tinged yellow or grey, rump yellow and usually with some pale and dark bars and dark shaft streaks, paler uppertail-coverts barred dark; dark brown primaries and secondaries broadly barred white, bars tinged green on outer webs of secondaries; uppertail dark brown, centre washed buff-grey or pearl-grey, pale brown bars on c. 3 outer feathers, occasionally on all feathers; yellow below, breast streaked blackish, belly sometimes orange-tinged, flanks and lower underparts whitish (often washed pale green) with heavy black bars; underwing barred brown and whitish, coverts tinged greenish; brown undertail barred at sides; short bill straight, slightly chisel-tipped, fairly broad across nostrils, bluish-black; iris brown, orbital skin grey; legs greenish to greyish-olive. Female is significantly smaller than male, shorter-billed, has most of crown black with very fine white streaks, more extensive barring below. Juvenile duller, more barred, has narrow dark bars above heavier on rump, sometimes hint of red on mantle, fully barred tail, more barred and streaked below, throat more brownish-black, smaller belly patch

often orange or orange-red; both sexes have adult-like head pattern but more black on forecrown, female soon acquiring white-streaked black crown. Race *insulaepinorum* is on average smaller, paler, with smaller red throat patch, paler yellow belly, also fully barred tail. VOICE. Short harsh "jorr" or "gwurr" in short series is commonest call; also higher "eh-eh-eh"; mewing or squealing "ta-há", like call of *Sphyrapicus varius*.

**Habitat.** Inhabits forest and woodland of most types, including mangroves and open woodland with palms; visits patches of cultivation and areas of habitation only rarely. Occurs from lowlands to mountains.

**Food and Feeding.** Diet consists of insects, reportedly of relatively large size. Also observed preying on eggs at nests of egrets (*Egretta*, *Bubulcus*) built in mangroves. Usually forages in pairs, but sometimes in parties of three to five individuals. Forages from low levels up to the canopy, on trunks and branches, and among vines and creepers. Pecks in crevices and beneath bark on dead wood, also gleans.

**Breeding.** Feb-Aug, possibly peak in May-Jun. Nest-hole 4-5 m up in palm, or in live or dead tree, apparently at times in nest of arboreal termites; territorial, attacks *Melanerpes superciliaris* in vicinity of nest. Clutch 3-4 eggs; incubation and fledging periods not documented; both parents feed chicks about equally.

**Movements.** Resident. Recorded rarely on Hispaniola after storms.

**Status and Conservation.** Not globally threatened. Common and widespread within range. Probably more numerous than *M. superciliaris*; is able to exploit wide variety of wooded habitats at all elevations. No known threats.

**Bibliography.** Alayón *et al.* (1986), Allen (1961), Anon. (1998b), Arredondo (1984), Barbour (1943), Berovides *et al.* (1982), Bond (1985), Cruz (1974a), Denis *et al.* (1999), Faaborg (1985), Garrido (1971, 1978), Garrido & Kirkconnell (2000), González-Alonso *et al.* (1992), Hernández (1999), Kirkconnell (2000b), Kirkconnell, Alayón *et al.* (1989), Kirkconnell, Garrido *et al.* (1992), Melián (2000), Posada & Kirkconnell (1993), Raffaele *et al.* (1998), Read (1914), Regalado (1977), Seth-Smith (1912), Stoltz *et al.* (1996), Wallace (2001).

## Tribe CAMPETHERINI

Genus *CAMPETHERA* G. R. Gray, 1841

## 61. Fine-spotted Woodpecker

*Campethera punctuligera*

French: Pic à taches noires

German: Pünktchenspecht

Spanish: Pito Salpicado

**Taxonomy.** *Picus punctuligerus* Wagler, 1827, Senegambia.Forms a superspecies with *C. nubica*, *C. bennettii* and *C. scriptoricauda*, and all sometimes considered conspecific. Races intergrade in Sudan and NE Zaire. Described race *batesi* (N Cameroon) synonymized with nominate. Two subspecies recognized.**Subspecies and Distribution.***C. p. punctuligera* (Wagler, 1827) - SW Mauritania (c. 60 km N of Rosso) and Senegambia E to SW Sudan and S to C Ivory Coast (Lamto), Ghana (Mole), S Nigeria (Abeokuta), C Cameroon (Mt Zoro and Mbakaou) and NE Zaire (upper Uele Valley).*C. p. balia* (Heuglin, 1871) - S Sudan to extreme NE Zaire.**Descriptive notes.** c. 22 cm; 56-74 g. Male has red forehead to nape, crown feathers with small grey bases, white supercilium faintly streaked at rear, blackish rear eyestripe, whitish ear-coverts, red malar stripe spotted black, white chin occasionally with fine black spots; buffy-white neck sides and throat spotted black; green or yellow-green upperparts, feathers tipped yellow, yellowish-white of shafts extending to feather webs to form variable number of bars; rump narrowly barred; brown flight-feathers barred yellowish-white or white; uppertail barred brown and yellow, prominent yellow shafts; underparts yellowish-white, whiter on belly and lower flanks, delicate small black spots on breast sometimes extending to flanks, where may be more bar-like; underwing pale yellow-white, barred dark; bill medium-long, culmen slightly decurved, broad base, narrower across nostrils, slate-grey, tip black; iris pinkish-red to violet, orbital skin grey; legs greenish-grey. Differs from *C. nubica* in whiter face, and by having spotting on underparts less extensive, with much smaller spots. Female has black forehead and forecrown with heavy white streaking, malar area spotted black and white. Juvenile as female, but darker, more olive, above, with darker barring, more buffish below, brownish or bluish-tinged (less green) legs, brownish-grey eyes, both sexes with unstreaked black forehead and forecrown, blacker eyestripe, more prominent black malar. Race *balia* is slightly smaller, has less yellow in upperparts, whiter underparts with larger spots over more extensive area; female's black forehead and forecrown distinctly spotted (not streaked) white. VOICE. Repeated "kweeyer" or "peer", like call of *Jynx torquilla* or Common Kestrel (*Falco tinnunculus*); more complex "wik-wik-whew-wee-yew, wee-yew" as contact between partners; soft "nyaa, nyaa, nyaa" or "tik-tik-tik" calls during encounters.**Habitat.** Wooded savanna, and acacia (*Acacia*) grassland with scattered or widely scattered trees and patches of bare ground; often around oil palms (*Elaeis guineensis*); also enters closed forest. Lowlands.**Food and Feeding.** Ants and their larvae, as well as termites (Isoptera), form bulk of diet, including that of nestlings. Commonly in pairs or family parties of up to 4 birds; sometimes joins mixed-species flocks. Forages in trees and bushes, often in oil palms; often searches base of trees, and descends to the ground to feed. Frequently visits termite mounds.**Breeding.** Season Jun-Aug in Senegambia, Apr-May in Sierra Leone, from Feb in Nigeria; Nov to early Apr or to Jun in Zaire. Nest excavated in tree or in termite mound. Clutch 2-3 eggs; incubation and fledging periods not recorded; juveniles stay with parents for a long time after leaving nest, but precise figures lacking.**Movements.** Resident; possibly some local seasonal movements in Senegambia.**Status and Conservation.** Not globally threatened. Generally considered to be common or at least locally common. Widespread and common in Senegambia; not uncommon in Sierra Leone; common and widespread in Nigeria. Occurs in numerous protected areas, e.g. Saloum Delta and Niokola Koba National Parks (Senegal), Comoé National Park (Ivory Coast), W National Park (Niger), Bénoué National Park (Cameroon), and Bamingui-Bangoran National Park (Central African Republic).**Bibliography.** Bannerman (1953), Barlow *et al.* (1997), de Bie & Morgan (1989), Carroll (1988), Cave & Macdonald (1955), Cheke & Walsh (1996), Dowsett & Dowsett-Lemaire (1993, 2000), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fry *et al.* (1988), Gee (1984), Green (1983, 1990), Giraudeau *et al.* (1988), Grimes (1987), King (2000), Koster & Grottenberger (1983), Lamarche (1980), Mackworth-Præd & Grant (1957, 1970), Nikolaus (2000), Pedersen (2000), Rodwell (1996), Salewski (2000), Scholte *et al.* (1999), Short (1973c, 1980, 1985b), Short & Horne (1988b), Snow (1978), Tarboton (1997), Thiollay (1985a).

## 62. Nubian Woodpecker

*Campethera nubica*

French: Pic de Nubie

German: Nubierspecht

Spanish: Pito de Nubia

**Taxonomy.** *Picus Nubicus* Boddaert, 1783, Nubia, north Sudan.Forms a superspecies with *C. punctuligera*, *C. bennettii* and *C. scriptoricauda*, and sometimes all considered conspecific. Identity of birds in E Rwanda uncertain; they probably belong either to *C. bennettii* or to nominate race of present species. Races poorly differentiated, and they intergrade; delimitation uncertain, complicated by apparent habitat-conditioned variation of nominate. Two subspecies currently recognized.**Subspecies and Distribution.***C. n. nubica* (Boddaert, 1783) - WC & NE Sudan, Ethiopia and NW & SW Somalia, S to NE Zaire (Beni, Rutshuru Plain), adjacent W Uganda, Kenya and C & SW Tanzania (Morogoro and Rukwa Valley); possibly this taxon in E Rwanda.*C. n. pallida* (Sharpe, 1902) - E & S Somalia and coastal Kenya.**Descriptive notes.** c. 23 cm; 46-71 g. Male has red forehead to nape, white supercilium, streaky black stripe from just in front of eye to rear crown side, white ear-coverts streaked dark at rear, red malar stripe spotted with black; white neck sides and hindneck heavily spotted black; buffish-white chin occasionally slightly spotted black (e.g. in Ethiopia), whitish throat spotted black; upperparts olive-brown, barred white and yellow, white on mantle, back and wing-coverts more as spots, rump more regularly barred; dark brown flight-feathers barred yellow or whitish; uppertail barred brown and yellow; underparts pale buff-white or yellowish-white, large black spots on breast and upper flanks, sometimes more as bars on lower flanks, small spots on undertail-coverts; underwing barred yellow and brown, sometimes plain yellowish; undertail as above, brown bars duller; medium-length bill fairly straight, broad base, broad across nostrils, grey to dark horn or sometimes blackish, tip black; iris red to pinkish, orbital skin grey; legs grey, tinged olive. In higher-lying areas throughout range, occurs in a darker form, darker above and with heavier spotting below. Distinguished from very similar *C. scriptoricauda* by less regular barring above. Female has forehead, forecrown and malar black with white spots. Juvenile generally darker than adult, more heavily marked below, breast often more streaked, streaks often extending to throat and chin, eyes greyish or grey-brown, both sexes with black forehead and crown either spotted or unspotted, white-spotted malar. Race *pallida* is on average slightly smaller than nominate, paler above, less strongly spotted below. VOICE. Loud, shrill, metallic, accelerating "wee-weee-weee...kweek", dying away at end, as contact between partners; various low "kwick" and "kweek" notes in close encounters. Drums occasionally.**Habitat.** Drier bushland, bushy grassland, riverine woodland, and open woodland; occurs in *Euphorbia-Acacia* woodland, open acacia savanna, also in areas with extensive growth of elephant grass (*Pennisetum*). From sea-level to 2300 m; to 1800 m in Ethiopia, to c. 2000 m in Somalia, to 1530 m in SW Uganda (Ruvenzori Range).**Food and Feeding.** Diet almost entirely ants; also termites (Isoptera), other insects; also spiders. Observed mainly singly, but pair-members keep vocal contact. Forages on trunks and limbs of trees; occasionally descends to ground. Spends much time investigating cracks in bark, stubs and similar sites; foraging techniques include gleaning and pecking.**Breeding.** Nov-Mar in Ethiopia; Jan-Feb, and eggs found also end Jun and mid-Nov, in Somalia; Jun-Jul in Uganda; from Feb in Zaire; in E Africa, during or shortly after main rainy season or in the small rains; possibly sometimes 2 broods in a season, e.g. in Somalia. New hole excavated every season, mainly by male, in rotten stump, fence post, or trunk of tree or palm, usually where natural cavities already present; territory large. Clutch 2-5 eggs, usually 2 or 3; incubation by both sexes, male roosting in nest at night, period not documented; both parents feed chicks, nestling period unrecorded; adults accompany young sex for sex in post-fledging period. Nests parasitized by Lesser and Scaly-throated Honeyguides (*Indicator minor*, *I. variegatus*).**Movements.** Resident.**Status and Conservation.** Not globally threatened. Common to very common and patchily distributed throughout Somalia; fairly common and widespread in E Africa; race *pallida* uncommon in coastal Kenya. Occurs in Awash National Park (Ethiopia), Murchison Falls National Park (Uganda), Samburu Reserve (Kenya) and Serengeti and Arusha National Parks (Tanzania).**Bibliography.** Archer & Godman (1937-1961), Ash & Miskell (1983, 1998), Britton (1980), Brown & Britton (1980), Carroll (1988), Cave & Macdonald (1955), Cheesman & Selater (1935), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Friedmann (1930a), Fry *et al.* (1988), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Præd & Grant (1957, 1970), Nikolaus (1987), Schels & Lavoyer (1987), Short (1973c, 1980, 1985b), Short & Horne (1988b), Short *et al.* (1990), Smith (1957), Snow (1978), Stevenson & Fanshawe (2001), Tarboton (1997), Urban & Brown (1971), Vande weghe (1992), Wilson & Wilson (1992), Zimmerman *et al.* (1996), Zinner (2001).

## 63. Bennett's Woodpecker

*Campethera bennettii*

French: Pic de Bennett

German: Bennettspecht

Spanish: Pito de Bennett

**Taxonomy.** *Chrysotilus Bennettii* A. Smith, 1836, western Transvaal.Forms a superspecies with *C. punctuligera*, *C. nubica* and *C. scriptoricauda*; sometimes treated as conspecific with last-mentioned, or with all three. Identity of birds in E Rwanda uncertain; they probably belong either to *C. nubica* or to nominate race of present species. Proposed race *uniamwestica* (Angola E to L Victoria and S to C Zambia) synonymized with nominate. Two subspecies currently recognized.**Subspecies and Distribution.***C. b. bennettii* (A. Smith, 1836) - WC Angola E to SE Zaire and Rwanda, possibly also Uganda (Merama Hills), and to W & S Tanzania, S to W Malawi, NE South Africa and S Mozambique; possibly this taxon in E Rwanda.*C. b. capricorni* Strickland, 1853 - S Angola, SW Zambia, and adjacent N Namibia and N Botswana.**Descriptive notes.** c. 24 cm; 61-84 g. Male has red forehead, crown and nape, forehead with small grey feather bases, broad red malar stripe with scattered black feather bases; neck side spotted black; rest of head side, including supercilary area, and chin and throat white, occasionally traces of brown on ear-coverts and throat, or throat yellow-buff; upperparts and wing-coverts barred olive-brown, yellow and white, coverts usually more spotted and pale-fringed; rump and uppertail-coverts similarly barred, but in arid zones often very pale and unbarred; brown flight-feathers edged greenish, yellowish-white bars on inner webs; uppertail variably dull to bright yellow, narrower brown bars; underparts pale yellowish-white, breast often tinged golden-buff and with bold, round to elongated dark spots, spots usually more bar-like on flanks; white undertail-

coverts often spotted or barred; underwing as above or paler; undertail yellowish, often tipped black; medium-length bill pointed, culmen moderately curved, narrow between nostrils, slaty-grey, paler near base; iris red, orbital skin grey; legs bluish-green to grey-green. Differs from *C. nubica* mainly in whiter face, less distinct patterning above. Female differs in having white-spotted black forehead and crown, white malar with black flecks, and brown to blackish-brown colour from bill to ear-coverts and chin and throat; ear-coverts and throat darker in W of range, becoming paler to E. Juvenile has black head top, is

somewhat darker and more spotted (less barred) above, more coarsely spotted below, eyes dark brown, male with blackish malar, few or no crown spots, female with white-spotted crown and at least indication of adult's brown head markings. Race *capricorni* is slightly larger than nominate, has paler, whitish, rump and uppertail-coverts, generally deeper yellow underparts with fewer or, sometimes, no spots; female has, on average, heavier white spotting on forehead and crown and much blacker ear-coverts and throat, but some are similar to darkest-throated nominate. Voice. Most frequent are "chuur" notes, and long series varying from "wi-wi-wi-wi" or "kee-kee-kee" to "ddrahh, ddrahh, ddray-ay, ddray-ay, dray-ay"; during encounters, high-pitched repeated "wirrit" or "whirrrwhirrrwhir-it-whir-it-whir-it-whirrrrrrrrr" chatter, and "wicka"-type calls. Drums softly, infrequently.

**Habitat.** Well-developed mature woodland and bush country. Typically, miombo (*Brachystegia*) and gusu (*Baikiaea*) woodland; in dry *Acacia* woodland, mainly in taller parts. Appears to replace *C. abingoni* in *Brachystegia* woodland on sandy soils and in less diverse closed woodland e.g. in parts of Zimbabwe, although the two occur together in many other areas, especially in valley woodland. Up to 1600 m in E Africa.

**Food and Feeding.** Primarily ants, and termites (Isoptera) and their eggs; occasionally other insects and larvae. Rather social, regularly in pairs or family parties of c. 3-5 birds; frequently accompanies glossy-starlings (*Lamprolornis*) when foraging. Highly terrestrial, commonly searches grassy sites or bare ground with patches of short grass, hops clumsily; ground-feeding accounts for 70-85% of foraging effort. Arboreal feeding mostly on trunks and larger branches of trees; main techniques are gleaning, and probing in cracks.

**Breeding.** Aug-Feb; peak in Oct-Nov in S. Hole excavated by both sexes, at 2-10 m in dead tree or in dead section of live tree, old hole often reused; hole made by other species of woodpecker, or natural cavity, also used; cavity depth 13-20 cm. Clutch 2-5 eggs, usually 3; both parents incubate, period 15-18 days; both also feed chicks, nestling period not documented; young remain with parents until start of next breeding attempt.

**Movements.** Resident; some short-distance post-breeding movement from arid areas to more favourable ones.

**Status and Conservation.** Not globally threatened. Everywhere variable in abundance, and with patchy distribution; locally common, in some places rare; absent from large parts of general range.

**Bibliography.** Benson & Benson (1977), Benson *et al.* (1971), Brewster (1991), Britton (1980), Brown (1993), Dean (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Ginn *et al.* (1989), Harrison *et al.* (1997), Harwin (1972), Hines (1995, 1996), Irwin (1978), Leonard (1998b), Lippens & Wille (1976), Mackworth-Præd & Grant (1957, 1962, 1970), Maclean (1993), Penry (1994), Pinto (1983), Schouteden (1966), Short (1971a, 1973c, 1980, 1985b), Short & Horne (1988b), Short *et al.* (1990), Snow (1978), Stevenson & Fanshawe (2001), Tarboton (1997, 2001), Tarboton *et al.* (1987), Vande weghe (1992).

## 64. Reichenow's Woodpecker

### *Campethera scriptoricauda*

**French:** Pic de Reichenow **German:** Reichenowspecht **Spanish:** Pito de Tanzania  
**Other common names:** Speckle-throated/Tanzanian Woodpecker

**Taxonomy.** *Dendromus scriptoricauda* Reichenow, 1896, no locality = Bumi, Tanzania.

Forms a superspecies with *C. punctuligera*, *C. nubica* and *C. bennettii*; frequently treated as conspecific with *C. bennettii*, and sometimes with all three. Monotypic.

**Distribution.** Inland E & S Tanzania S to S Malawi (S to Nsanje area) and C Mozambique; recorded also at base of Mt Kilimanjaro, in N Tanzania.

**Descriptive notes.** c. 22 cm. Male has red forehead to nape, forehead with small grey feather bases, white supercilium, dark stripe behind eye, dark-streaked ear-coverts, red malar stripe with scattered black feather bases; white neck side, chin and throat all spotted black; upperparts barred dark olive, yellow and white, wing-coverts more spotted; brown flight-feathers barred yellowish-white on inner webs; uppertail barred yellow and brown; underparts pale yellowish-white with large rounded dark spots, ventral region usually paler; underwing as above or paler; medium-length bill slightly curved, narrow between

nostrils, slaty-grey, lower mandible mostly pale yellow or yellow-green; iris red, orbital skin grey; legs bluish-green to grey-green. Differs from very similar *C. bennettii* in slightly smaller size, shorter wing, dark eyestripe and ear-coverts, black-spotted chin and throat, larger spots below, yellow lower mandible. Female differs from male in pale-spotted black forehead and crown, white moustachial area, streaky black malar. Juvenile resembles female, but more spotted above, spots below more diffuse. **VOICE.** Frequent "churr" notes and chattering series, very like those of *C. bennettii*.

**Habitat.** Open woodland, savanna and thorn-scrub; occurs in open miombo (*Brachystegia*) woodland with grassy ground layer in S of range.

**Food and Feeding.** Mainly ants and their larvae. In pairs or family parties. Largely terrestrial, seeking food in grassy areas, hops clumsily on ground. In trees feeds mostly on trunks and larger branches, by gleaning and probing.

**Breeding.** Oct-Nov in Malawi. Nest-hole excavated in dead tree or palm trunk. Clutch 3 eggs; no other details, but likely to be much as for *C. bennettii*.

**Movements.** Apparently resident.

**Status and Conservation.** Not globally threatened. Reasonably common. Occurs in Mikumi National Park, in Tanzania. True status masked by confusion over taxonomic position; further research required, especially in areas where its range meets that of *C. bennettii*.

**Bibliography.** Archer & Godman (1937-1961), Britton (1980), Dowsett & Dowsett-Lemaire (1993), Fry *et al.* (1988), Ginn *et al.* (1989), Hockey (1996), Mackworth-Præd & Grant (1962), Maclean (1993), Newman (1996), Short (1973c, 1980), Short & Horne (1988b), Sinclair (1987), Sinclair & Hockey (1996), Stevenson & Fanshawe (2001), Zimmerman *et al.* (1996).

## 65. Golden-tailed Woodpecker

### *Campethera abingoni*

**French:** Pic à queue dorée **German:** Goldschwanzspecht **Spanish:** Pito Colidorado

**Taxonomy.** *Chrysotilus Abingoni* A. Smith, 1836, district of Zeerust, western Transvaal, South Africa.

Forms a superspecies with *C. mombassica* and *C. notata*. Often treated as conspecific with former, but differs in plumage and vocalizations; apparent hybrids between *C. mombassica* and race *suahelica* of present species recorded from EC Tanzania and from just S of Mt Kilimanjaro; further studies needed. Proposed race *ressmanni* (Central African Republic) not distinguishable from *chrysurus*; nor *annectens* (lower Congo and C Angola to Rwanda and Malawi) from nominate. In past, type locality of species erroneously listed as Durban, Natal; with rectification, hitherto accepted name *smithii* becomes junior synonym of nominate. Six subspecies currently recognized.

**Subspecies and Distribution.**

*C. a. chrysurus* (Swainson, 1837) - Senegambia and N Guinea, and recently recorded in NE Ivory Coast; also Central African Republic, S Sudan, NE Zaire and W Uganda.

*C. a. abingoni* (A. Smith, 1836) - lower R Congo and W Zaire E to W Tanzania, and S to NE Namibia, NW Zambia, Zimbabwe and N Transvaal.

*C. a. kavirondensis* van Someren, 1926 - E Rwanda, NW & NC Tanzania and SW Kenya.

*C. a. suahelica* (Reichenow, 1902) - N Tanzania (Arusha, Moshi, N Pare Mts) to E Zimbabwe, Mozambique and N Swaziland.

*C. a. anderssoni* (Roberts 1936) - SW Angola, Namibia (except NE) and SW Botswana to N Cape Province and SW Transvaal.

*C. a. constricta* Clancey, 1965 - S Swaziland, extreme S Mozambique and Natal.

**Descriptive notes.** 20-23 cm; 51-58 g (race *chrysurus*), 61-83 g (*abingoni*, *suahelica*). Male has red forehead to nape, feathers with greyish-black bases, white lores, thin white supercilium with dark upper border, thin black-streaked white line below eye, dark stripe behind eye, white or whitish ear-coverts, narrow red malar with dark feather bases, white neck sides streaked blackish, whitish chin and throat heavily spotted black; olive-brown upperparts narrowly barred pale yellow-white and greenish-yellow, pale bars broader on rump and uppertail-coverts, wing-coverts spotted and tipped yellowish; brown flight-feathers barred

whitish, bars broader on inner webs; uppertail brown, barred yellowish-white, bars sometimes obscured by overall yellow wash; white underparts tinged yellow on breast and flanks, heavy blackish streaking on breast, spots on flanks and belly; underwing as above, but paler; undertail yellowish-brown, obscurely pale-barred; moderately long bill broad-based, culmen slightly curved, slaty-black, base of lower mandible often tinged green; iris usually reddish but variable from hazel to blackish, orbital skin grey; legs dark greenish with olive or grey tinge. Differs from *C. mombassica* in darker appearance, barred upperparts. Female differs from male in having black forehead and crown with fine white spots, blackish malar. Juvenile as adult female, but less yellow above with spots and streaks instead of bars, more heavily streaked below, flanks and belly more barred, eyes brown or brownish-grey. Races differ mainly in tone of upperparts and in strength of markings below: *chrysurus* is smaller than nominate, greener above, ear-coverts streaked, blacker on throat and breast; *kavirondensis* has pale barring above broader, ear-coverts streaked, underparts more narrowly streaked; *suahelica* as previous but yellower-toned above; *constricta* is very like previous, but greener above; *anderssoni* resembles nominate, but greyer above, rump pale, markings below heavier, throat and breast almost wholly black. **VOICE.** Call loud and distinctive, single plaintive "dreee-aw" or "weeeea", often by male; series of 12-12 "yaoaaak-yaaaaaak" notes as long-distance call; more aggressive "weet-wit-wit" and "kyek" notes; intimate "pew-pew-pew". Drums in slow rolls 1-5 seconds long.

**Habitat.** Almost all kinds of woodland and forest edge. Occurs in coastal forest, evergreen forest and thickets, riparian forest, and in savanna with dense *Acacia* bush; also recorded in rich miombo (*Brachystegia*) woodland and montane forest, but in such habitats it keeps mostly to the edge. Some preference for vicinity of rivers in more open regions, but always in areas of dense trees and thickets. Occasionally visits parks, large gardens and exotic trees; also visits rather isolated trees for foraging. Generally replaced by *C. bennettii* in *Brachystegia* woodland, but sometimes occurs there. Occurs from sea-level up to 2000 m in E Africa; up to 1500 m in Malawi, to 1800 m in Zimbabwe, and to c. 1400 m in Natal.

**Food and Feeding.** Insects and their larvae, mainly arboreal ants; also millipedes (Diplopoda). Generally singly or in pairs; often associates with *Dendropicus fuscescens*. Forages mainly at middle and lower levels; explores larger branches and twigs, often moving along underside. Predominant techniques are probing and gleaning; also hammers forcefully on dead trunks or branches affected by wood-boring larvae, using this method more frequently than do congeners. Often flies rather long distances between foraging sites.

**Breeding.** Fledgling fed by adult in Jun in the Gambia; otherwise Aug-Dec. Nest-hole drilled into tree at height of 1-5 m; occupies relatively large territory, 10-15 ha. Clutch 2-5 eggs, usually 2 or 3; incubation by both sexes, only male at night, period c. 13 days; both parents also brood chicks, and feed them by regurgitation; nestling period 22-25 days. Nests parasitized by honeyguides (*Indicator*).

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Locally common; common in Angola; uncommon and local in Kenya and Tanzania; rare in W Africa. Common in Akagera National Park (Rwanda); occurs in Masai Mara Reserve (Kenya), Arusha National Park (Tanzania) and Liwonde National Park (Malawi). Common in Caprivi Strip (Namibia); common in South Africa, where present in numerous protected areas, e.g. Kruger National Park, Mkuzi Game Reserve and Umlalazi Nature Reserve. Recorded in Ivory Coast for first time in 1995, where present in Comoe National Park.

**Bibliography.** Anon. (1998a), Baillie (1983), Banerman (1953), Barlow *et al.* (1997), Benson *et al.* (1971), Brown (1993), Cave & Macdonald (1955), Clancey (1965, 1984e, 1988b), Dean (2000), Dowsett & Dowsett-

## 66. Mombasa Woodpecker

*Campethera mombassica*

French: Pic de Mombasa

German: Mombasaspecht

Spanish: Pito de Mombasa

**Taxonomy.** *Picus* (*Campothera*) [sic] *mombassicus* Fischer and Reichenow, 1884, Mombasa.

Forms a superspecies with *C. abingoni* and *C. notata*. Often treated as conspecific with former, but differs in plumage and vocalizations; apparent hybrid individuals with appearance intermediate between *C. abingoni suahelica* and present species recorded from EC Tanzania and from just S of Mt Kilimanjaro; further study required. Monotypic.

**Distribution.** S Somalia, coastal Kenya (including R Tana inland to Garissa) and NE Tanzania (S to about Dar es Salaam, W to W Usambara Mts, possibly also at E Mt Kilimanjaro).

**Descriptive notes.** c. 22 cm; 50-71 g. Male has olive-green forehead and crown feathers with broad red tips, red nape, buffish lores, short white supercilium, whitish sides of head and neck with black streaks, short red malar stripe streaked black; whitish chin and throat, sometimes with few dark streaks or spots; bright golden-green upperparts with fine yellowish-white spots and shaft streaks; brown flight-feathers with some spots; uppertail golden-green to olive-brown, outer feathers faintly barred; white or buffy-white below, breast and flanks tinged yellowish, fairly broad blackish streaks narrower on flanks and belly; underwing as above, coverts paler;

undertail brownish, suffused yellow; medium-length bill broad-based, culmen slightly decurved, slate-grey, distinct green tone on lower mandible; iris dark reddish, orbital skin grey; legs greenish to olive or olive-grey. Distinguished from similar *C. abingoni* by much brighter upperparts with small dots, not bars, paler throat, olive-green bases of crown feathers, different vocalizations. Female differs in having dark olive-green forehead and crown with small yellow-buff spots, olive-grey malar with black and white streaks and spots. Juvenile resembles female, but duller, more spotted above, more heavily streaked below, sometimes some bars on lower underparts, eyes more brownish or greyish. Voice. Accelerating series ending with short "yuk", distinctly different from *C. abingoni*, initial notes less buzzing; intimate calls include grating "drrrrddt". Very rarely, if ever, drums.

**Habitat.** Coastal forest and woodland.

**Food and Feeding.** Mostly ants and their larvae. Usually found singly; joins mixed feeding parties. Forages at middle and lower levels, in large and small trees, often within cover of foliage. Main techniques are probing and gleaning; sometimes hammers on dead branches.

**Breeding.** Season Dec-Feb. Nest-hole in tree; no other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon or rare in Somalia, where few recent records; possibly overlooked among much commoner *C. nubicus*. Locally fairly common in Kenya and Tanzania. Occurs in several protected areas, e.g. Shimba Hills National Park and Arabuko-Sokoke Forest (Kenya) and Pugu Forest Reserve (Tanzania). Although not officially considered at risk, this species' limited range means that any degradation or erosion of its coastal woodland habitat could lead to a potentially serious decline in its population.

**Bibliography.** Ash & Miskell (1983, 1998), Bennun & Njoroge (1999), Clancey (1988b), Cordeiro & Githiru (1998), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Evans, Hague *et al.* (1994), Evans, Tye *et al.* (1997), Fanshaw (1994), Fry *et al.* (1988), Lewis & Pomeroy (1989), Moreau (1935), Seddon (2001), (1996), Short (1980), Short & Horne (1988b), Short *et al.* (1990), Snow (1978), Stevenson & Fanshawe (2001), Tarboton (1997), Waiyaki & Bennun (2000), Williams (1997), Zimmerman *et al.* (1996).

## 67. Knysna Woodpecker

*Campethera notata*

French: Pic tigré

German: Knysnaspecht

Spanish: Pito de Knysna

**Taxonomy.** *Picus notatus* M. H. K. Lichtenstein, 1823, southern South Africa.

Forms a superspecies with *C. abingoni* and *C. mombassica*. Variation in plumage darkness and markings rather large, but based on individual rather than geographical differences, so that no races are recognizable. Monotypic.

**Distribution.** S South Africa, from Swellendam region E to extreme S Natal.

**Descriptive notes.** 20-22 cm; 62 g. Male has red forehead to nape, feathers of forehead with extensive dark olive-brown bases, buffish-white lores, narrow white supercilium with dark spotting, red malar stripe sometimes obscured by heavy white and black spotting on feather bases; buffish-white sides of head heavily spotted and streaked dark, whitish neck sides with prominent black spots; whitish chin and throat heavily spotted black, especially on throat; pale-spotted olive hindneck; green or yellow-green upperparts with fine pale yellow spots (rarely, form broken bars), mantle very occasionally with slight trace of red, rump and uppertail-coverts finely barred

whitish; scapulars and upperwing-coverts with small pale spots often streak-like; dark brown flight-feathers edged green, barred white, bars broader on inner webs; uppertail yellowish-olive, narrowly barred yellowish; whitish below, breast buffish-tinged, large dark brown spots on breast and flanks, narrower streaks on belly and undertail-coverts; underwing as above but paler; undertail washed yellow, barring obscured; longish bill narrow, culmen slightly curved, dark slate-grey, tip black; iris reddish, orbital skin grey; legs green-grey. Distinguished from *C. abingoni* by darker appearance, greener upperparts spotted, not barred, heavily spotted face, neck and underparts. Female has forehead and

crown olive-brown with fine pale yellowish to white spots, malar spotted black and white with no red. Juvenile resembles female, but upperparts greener, less yellow, with fewer spots, larger spots and barring below. Voice. Common call an almost whistled "wlee" or "peeah", weaker but shriller than that of *C. abingoni*; triple-note "weee-we-wi" series, and "kra kra kree-kree-kree-kree kra kra", between croaking and whistling; nestling calls likened to puffing engine.

**Habitat.** Inhabits light forest, evergreen forest, and dense bush; also riparian woodland and bush; found also at large trees in comparatively open country, and in *Euphorbia* scrub. Occasionally enters gardens.

**Food and Feeding.** Mainly ants and their brood, also wood-boring beetles and their larvae. Occurs singly or in pairs, also in small family parties; occasionally accompanies mixed-species flocks. Forages at medium levels in trees, often dead ones, both on branches and on trunks; movements quick, perches crosswise at times. Frequently pecks and probes among lichens.

**Breeding.** Aug-Nov. Nest excavated by both sexes, in dead trunk or branch of tree. Clutch 2-4 eggs; incubation period probably 12 days; both parents feed chicks, by regurgitation, and both also tend to nest sanitation; nestling period 3-4 weeks.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in South African Forests EBA. Locally common; unobtrusive. Appears to be thinly dispersed within its small coastal range, where suitable sites for hole-excavating are often sparsely scattered. Total range covers c. 50,000 km<sup>2</sup>, within which this species' population is thought to be between 1500 and 5000 individuals; c. 30-60% of these probably live in protected reserves, e.g. known to be present in Oribi Gorge Nature Reserve (South Africa). By early 20th century, clearance of habitat, both forest and bush, for settlements and agriculture had reduced its range, and much more habitat has been lost since then. With the remaining population so small, and habitat loss likely to continue, regular monitoring is required in order to assess whether any conservation action becomes necessary in the future.

**Bibliography.** Brooke (1984), Clancey (1958a, 1988b, 1992), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Furlong (2000), Ginn *et al.* (1989), Harrison *et al.* (1997), Hockey (1996), Hockey *et al.* (1989), Mackworth-Praed & Grant (1962), Maclean (1993), Martin & Martin (1993, 1996), Newman (1996), Nichols (1983a, 1983b), Schmidt (1961), Schultz (1991), Short (1980, 1985b), Short & Horne (1988b), Sigfried (1992), Sinclair (1987), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Skead (1964), Snow (1978), Stattersfield & Capper (2000), Tarboton (1997, 2001).

## 68. Little Green Woodpecker

*Campethera maculosa*

French: Pic barré

German: Goldmantelspecht

Spanish: Pito de Guinea

**Other common names:** (African) Golden-backed Woodpecker

**Taxonomy.** *Picus maculosus* Valenciennes, 1826, Senegal.

Forms a superspecies with *C. cailliauti*. Hybridizes rarely with latter in Ghana. Monotypic.

**Distribution.** Senegal and W Guinea-Bissau E in coastal zone to C Ghana (Aburi region); extends inland to Mt Nimba (Liberia).

**Descriptive notes.** c. 16 cm; 54 g. Fairly distinctive, small-bodied woodpecker. Male has olive-blackish forehead and crown with small red feather tips, red nape rather poorly defined; rest of head, neck, chin and throat buff with dense brown spotting; upperparts bright yellowish-green to bronze-green, occasionally a few whitish spots on mantle, sometimes slight traces of red, rump faintly barred; brown flight-feathers with pale buffish bars, broadest on inner webs; uppertail blackish, indistinct yellow shafts, green outer feathers; underparts buffish, greenish-white below breast, and all heavily barred deep olive;

underwing-coverts pale yellowish-white, sometimes with few indistinct bars; undertail blackish, tinged yellow; short bill relatively broad-based, fairly broad across nostrils, dark olive-green to blackish, lower mandible with bluish or olive tint; iris brown or pinkish-brown, orbital skin greyish; legs olive-grey or greenish. Female lacks red on head, has forehead and crown olive-black and nape deep olive, all spotted with buff, also greater tendency towards some spotting on upperparts. Juvenile is much as adult, but greener, less bronzy above, usually some paler streaks on back, generally paler and less buff below with barring less even, eyes dark brown. Voice. Common call regular series of 3-4 ascending "teeay" notes, faster than in *C. cailliauti*; also repeated "teerweet" in aggression.

**Habitat.** Most forest types, mainly at edges. Inhabits edges of primary and secondary forest, clearings with second growth and dead trees, and forest-shrub mosaic; also open forest fringing rivers. Occurs in all lowland forests in Sierra Leone, also in gallery forest, open woodland, degraded forest, and in small hillside trees, even in mangroves; also in farmland in Liberia. Ventures into open country where lots of trees are present. Occurs from lowlands up to mountain ridges above 1000 m; up to 1200 m in Liberia.

**Food and Feeding.** Known to feed on ants, primarily of genus *Crematogaster*. Usually encountered singly or in pairs, sometimes in mixed-species parties. Forages from canopy down to lower levels, occasionally low in shrub layer, mostly at 5-25 m; at times descends to ground. Uses branches of 2-20 cm in diameter; often perches upright across branches. Main feeding techniques are gleaning and pecking.

**Breeding.** Recorded in Aug in Senegal (1 record); Dec and Feb in Sierra Leone; in Liberia, nest-excavation seen in May and Oct, adults feeding nestlings in early Aug. Nest excavated in tree, or in arboreal nest of ants or termites (Isoptera). No other information.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Not uncommon in Sierra Leone; not uncommon in Liberia; very few records from Senegal, all since late 1960's. Relatively little known, and possibly overlooked in some areas. Occurs in Gola Forests Reserves (Sierra Leone), and Tai Forest National Park and Yapo Forest Reserve (Ivory Coast). Probably best studied in Liberia, where densities of 2-3 pairs/km<sup>2</sup> found in forest edges, clearings and farmland; total Liberian population estimated at c. 50,000 pairs. Appears to benefit from logging and clearance of forest, at least temporarily, since it favours more open habitats.

**Bibliography.** Allport *et al.* (1989), Bannerman (1953), Barlow *et al.* (1997), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Garthorse *et al.* (1995), Gatter (1997), Grimes (1987), Halleux (1994), Lamarche (1980), Mackworth-Praed & Grant (1970), Short (1980, 1985b), Snow (1978), Tarboton (1997), Thiollay (1985a, 1985b).

## 69. Green-backed Woodpecker

*Campethera cailliautii*

French: Pic de Cailliaut

German: Tüpfelspecht

Spanish: Pito de Cailliaud

Other common names: Little Spotted Woodpecker

**Taxonomy.** *Chrysopicos Cailliautii* Malherbe, 1849, Mombasa.

Forms a superspecies with *C. maculosa*. Has hybridized rarely with latter in Ghana. Distinctive race *permista* often thought to be separate species, but interbreeds freely with *nyansae* in Angola and Zaire. Proposed race *togoensis* (Ghana E to S Nigeria) regarded as synonymous with *permista*; and *kaffensis* (SW Ethiopia) with *nyansae*; *fulleborni* (sometimes misspelt *fulleborni*), from W Tanzania to Zambia, is also synonymized with *nyansae*. Orange-naped form "*quadrosi*", known only from the Mozambique type specimen, is considered to be an aberrant form of *loveridgei*. Four subspecies recognized.

**Subspecies and Distribution.**

*C. c. permista* (Reichenow, 1876) - E Ghana E to extreme SW Sudan, SW Uganda, and S to N Angola and C Zaire.

*C. c. nyansae* (Neumann, 1900) - SW Ethiopia, SW Kenya and NW Tanzania through E Zaire to N Zambia and NE Angola.

*C. c. loveridgei* Hartert, 1920 - C Tanzania (Kilosa area) S to extreme E Zimbabwe (Mt Zelinda) and Mozambique (S to R Limpopo).

*C. c. cailliautii* (Malherbe, 1849) - coastal zone from S Somalia (lower R Jubba and Boni Forest) S to NE Tanzania, including Zanzibar I.

**Descriptive notes.** c. 16 cm; 34-57 g. Male has black forehead and crown feathers tipped red, red nape, buffish lores, white supercilium, buffish-white sides of head to chin and upper throat all densely spotted with black, yellow-buff neck sides and hindneck heavily spotted black; bright green upperparts with small, neat yellowish-white spots, rump and uppertail-coverts yellow and faintly barred; brown flight-feathers edged yellow-green on outer webs, barred whitish; uppertail greenish-brown, sides barred yellow; pale yellow below, belly whiter, with regular dark brown spots, spots smaller on belly and flanks;

underwing-coverts pale yellowish, spotted blackish; grey or blackish, tip dark; iris reddish to brownish, orbital skin greyish-white; legs grey to olive-grey or green. Female differs in having black forehead and crown with white spots. Juvenile duller and greener above than adult, forehead and crown as female but spots finer and whiter, red on nape reduced or lacking, eyes more brown or even greyish. Race *loveridgei* is slightly bigger than nominate, yellower above, with spots forming more bar-like pattern, tail greener, spots be-

low less regular; *nyansae* is slightly longer-winged than previous, greener, less yellow, above with markings often in form of narrow streaks, more heavily spotted below with spots tending to form bars, also bill broader across nostrils; *permista* distinctive, with greyer face, unmarked green upperparts, completely dark-barred underparts (some in S Nigeria are paler below with narrower barring), bill also broad across nostrils. Voice. Thin, plaintive "hee" or "hlee", repeated c. 4-12 times at regular intervals; grating "grrrr" or "dddn" calls in encounters, including aerial ones; also "tew-a", "wik-a" and variations, sometimes faster in long series; "aaaa" or "aa-aa" in intimate contacts. Drumrolls short, soft.

**Habitat.** Wide range of habitats, from forest to thornbush savanna; often near water in dry country. Occupies e.g. rich miombo (*Brachystegia*) woodland and mahobohobo (*Uapaca*) woodland in S parts of range; elsewhere, edges of lowland or other evergreen forest, woodland, wooded grassland, locally palm groves. Strongly associated with riparian forest in Malawi. Enters gardens. To 1750 m in Malawi and most of E Africa, but found at up to 2100 m in SW Uganda; to 1000 m in Zimbabwe, locally to 1200 m.

**Food and Feeding.** Diet consists largely of arboreal formicid ants and termites (Isoptera). Observed singly or in pairs. Forages high in the canopy; also in thickets and denser patches of vegetation, where easily overlooked. Visits live and dead sections of trees, also ant and termite nests. Gleaning seems to be the principal foraging technique; also pecks. Observed attacking seed pods in search of insects.

**Breeding.** Feb-Aug in Angola; Sept-Nov in E and probably Mar-Sept in Zaire, with egg-laying associated with rainy seasons. Nest excavated in tree or palm. Clutch 2-3 eggs, occasionally 4; both sexes incubate, and both feed nestlings probably by regurgitation; incubation and fledging periods not documented.

**Movements.** Resident; some short-distance wandering.

**Status and Conservation.** Not globally threatened. Generally localized and uncommon. Rare in Somalia, where very few records; uncommon and local in E Africa, possibly more common in some places, but distribution discontinuous. Fairly widespread and not uncommon in S parts of range. Possibly overlooked owing to its unobtrusive behaviour, may possibly be more common than it appears. Race *permista* uncommon to locally not uncommon in Nigeria, common in Angola, locally common in Cameroon and Gabon. Present in numerous protected areas throughout extensive range, e.g. Bamingui-Bangoran National Park (Central African Republic), Impenetrable Forest National Park (Uganda), Masai Mara Reserve (Kenya), Pugu Forest Reserve (Tanzania), Ruvuvu National Park (Burundi) and Akarega National Park (Rwanda).

**Bibliography.** Anon. (1998c), Ash & Miskell (1983, 1998), Bannerman (1953), Benson & Benson (1977), Chapin (1952), Cheke & Walsh (1996), Christy & Clarke (1994), Clancey (1971b, 1980a), Davies & Boon (1999), Dean (2000), Dowsett (1972b, 1989b), Dowsett & Dowsett-Lemaire (1991, 1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1999, 2000), Elgood *et al.* (1994), Evans *et al.* (1994), Fry *et al.* (1988), Ginn *et al.* (1989), Harrison *et al.* (1997), Irwin (1981), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981b), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), Moreau (1935), Newman (1996), Nikolaus (1987), Pakenham (1979), Pinto (1983), Prigogine (1987), Sargeant (1993), Schouteden (1966), Short (1980, 1985b), Short & Horne (1988b), Short *et al.* (1990), Sinclair (1987), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Snow (1978), Solomon (1998), Sørensen *et al.* (1996), Stuart & Turner (1980), Tarboton (1997), Thiollay (1985b), Urban & Brown (1971), Vande weghe (1992), Vernon *et al.* (1989), Wilkinson & Beecroft (1988), Zimmerman *et al.* (1996).

PLATE 30

inches 3  
 cm 8

below 15 m; inspects trunks, vines and saplings. Main techniques are probing, gleaning and pecking.

**Breeding.** Few data. Season Dec-Jun in Sierra Leone and Liberia; Aug-Feb in Zaire; nest building in Nov in Gabon. Nest at low to medium height, 3-7 m, in tree or dead stump; clutch 2-3 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally uncommon, though locally common, e.g. in Sierra Leone and Gabon. Reasonably common in Liberia, with densities of 3-6 pairs/km<sup>2</sup>, and estimated population of 100,000 pairs. Rare in Nigeria. Not uncommon in Angola. Occurs in Korup National Park (Cameroon), La Lopé National Park (Gabon) and Kibale Forest National Park (Uganda).

**Bibliography.** Allport *et al.* (1989), Ash (1990), Ash & Sharland (1986), Aspinwall & Beel (1998), Bannerman (1953), Britton (1980), Colston & Curry-Lindahl (1986), Dean (2000), Dowsett (1973, 1979b, 1989b), Dowsett & Dowsett-Lemaire (1991, 1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1999, 2000), Elgood *et al.* (1994), Fry *et al.* (1988), Garishore *et al.* (1995), Gatter (1988, 1997), Germain & Cornet (1994), Grimes (1987), Heigham (1976), Leonard & Van Daele (1999), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981b), Mackworth-Præd & Grant (1957, 1962, 1970), Nikolaus (1987), Pinto (1983), Short (1980, 1985b), Short *et al.* (1990), Snow (1978), Sørensen *et al.* (1996), Tarboton (1997), Thiollay (1985b), Zimmerman (1972), Zimmerman *et al.* (1996).

## Genus *GEOCOLAPTES* Swainson, 1832

### 73. Ground Woodpecker

#### *Geocolaptes olivaceus*

French: Pic laboureur

German: Erdspecht

Spanish: Pito Terrestre

Other common names: African Ground Woodpecker

**Taxonomy.** *Picus olivaceus* J. F. Gmelin, 1788, Cape of Good Hope. No close relatives. Two subspecies recognized.

**Subspecies and Distribution.**

*G. o. olivaceus* (J. F. Gmelin, 1788) - W & SC Cape Province.

*G. o. prometheus* Clancey, 1952 - S Cape Province NE to N Transvaal and W Swaziland.

**Descriptive notes.** 22-30 cm; 105-134 g. Male has brownish-grey forehead and crown, browner nape often with slight trace of red, grey sides of head and neck, dark grey malar with fine red feather tips (red visible only at close range); white chin and throat; upperparts greyish-brown to dull green-brown, in fresh plumage with pale feather tips forming small spots and hint of barring; red rump, white-barred brown uppertail-coverts; wing-coverts spotted or barred pale; dark brown flight-feathers all barred whitish, tertials also tinged greenish; uppertail brown, prominent narrow whitish bars; whitish breast feathers broadly tipped

pinkish-red with some pale streaks, belly deeper crimson with pale bases, flanks barred grey-brown and whitish, bars often extending to undertail-coverts; underwing brown and yellowish-white; undertail light brown, barred yellowish-white; long bill pointed, culmen curved, very narrow between nostrils, black, greyer base; iris pink to golden, whiter near pupil; legs grey. Female is very like male, but lacks red malar tips. Juvenile has adult pattern but duller, usually some red on nape, paler and more light pinkish below, eyes all white. Race *prometheus* is much paler, especially below; upland populations tend to be darker overall. **VOICE.** Loud, harsh "peer, peer, peer" or "pee-aa-r-g-h" screams when flushed; loud series of up to 5 "ree-chick, ree-chick" notes, as contact and territorial call; also falcon-like "krrreee" when joining group; "chew-kee" calls when displaying. **Habitat.** Open rocky terrain in uplands, including grassy boulder-strewn slopes and hillsides, open grassland with rocky ridges, mountain slopes, barren or eroded areas; recorded also around reedy marshes. Also roadsides in lowlands in SW of range. To c. 2100 m, in Natal from 1200 m upwards; rarely recorded as low as 600 m, but descends to sea-level in SW of range.

**Food and Feeding.** Highly specialized on ants, ant broods and alates; termites (Isoptera), beetles and other insects, and mites (Acari) also taken. Ants of 8 genera comprise 95% of food taken, and include *Camponotus*, *Anoplolepis*, *Acantholepis*, *Tetramorium*, *Crematogaster*, *Pheidole*; total of c. 60 ant species has been recorded in diet. Termites regularly eaten, but form only 1-25% of total food intake; other arthropods probably taken accidentally. Usually in pairs or small parties of c. 6 birds, groups occupying area of 21-70 ha; groups appear to know exact locations of ant nests within their home range, spend at most 3 days in a particular place. Perches upright on large boulders, flies from one rocky outcrop to the next. Forages mostly on ground, occasionally on dead trees; moves on ground primarily by hopping, also walks on more level terrain. Explores any fault, crevice or hole, including interfaces between stones and the soil; makes single inquisitive pecks, sweeps away debris with the bill. Penetrates soil with heavy pecks when an ant colony detected; then feeds in characteristic posture, head down and beak deeply implanted in ground, continuous activity of tongue indicated by jerky tail movements. Wood-dwelling ants (*Crematogaster*) obtained by probing into dead wood. Surface gleaning only a minor feeding technique used. Forages mostly in morning hours, with secondary peak of activity in late afternoon; during these periods large quantities of ants consumed, digested slowly; even during cooler season (Mar-Aug), requires only c. 35% of total daylight hours to procure sufficient food.

**Breeding.** Aug-Sept in Cape Province and Transvaal; Aug-Dec, mainly Oct-Nov, in Natal. In pairs or trios, copulations occurring during excavation phase of cycle; pre-copulation display by male in upright stance with spread wings. Nest dug mainly by male, in bank, often in road cutting, or in vertical wall of donga, or among rocks; tunnel usually c. 1 m long, range 50-120 cm, 7-5 cm in diameter, ending in enlarged nest-chamber 15 cm in diameter; same nest may be used over several seasons, and also serves as roost. Clutch 2-5 eggs, usually 3; both parents incubate, sometimes possibly with 1 or more helpers; chicks fed by both parents and helper; incubation and fledging periods apparently not documented; juveniles stay with parents until the next breeding season.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common in most of range. Its use of essentially unthreatened, often remote, habitats implies that species is probably secure in most areas. Few

historical data available; no evidence of any significant decline in range or numbers. Occurs in several protected areas, e.g. Giant's Castle and Suikerbosrand Reserves.

**Bibliography.** Barnes (1999), Brooke (1984), Brown & Barnes (1984), Clancey (1952, 1988a, 1992), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Earle (1986), Every (1974), Fry *et al.* (1988), Ginn *et al.* (1989), Harrison *et al.* (1997), Hockey (1996), Hockey *et al.* (1989), Mackworth-Præd & Grant (1962), Maclean (1993), Newman (1996), Oatley (1995), Oatley *et al.* (1989), Short (1971e, 1980, 1985b), Sinclair (1987), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Tarboton (1997, 2001), Tarboton, Allan *et al.* (1993), Tarboton, Kemp & Kemp (1987).

## Genus *DENDROPICOS* Malherbe, 1849

### 74. Little Grey Woodpecker

#### *Dendropicos elachus*

French: Pic gris

German: Wüstenspecht

Spanish: Pito Saheliano

Other common names: Least (Grey) Woodpecker

**Taxonomy.** *Dendropicos elachus* Oberholser, 1919, Senegal and coast of Guinea.

Monotypic.

**Distribution.** SW Mauritania, Senegambia, and in narrow belt from C Mali E to C Chad and WC Sudan and S to NE Nigeria (to Aliya) and extreme N Cameroon (S to around Maroua); possible presence between Senegambia and C Mali requires confirmation.

**Descriptive notes.** 12-14 cm; 17-21 g. Male has pale grey-brown forehead to mid-crown, dull red hindcrown and nape, white supercilium from behind eye to rear of ear-coverts, pale brown-grey lores, ear-coverts and sides of neck, whitish stripe from lower lores below ear-coverts, thin dark brown malar stripe; head markings fade rapidly, leaving plain-faced appearance; white chin and throat faintly streaked brown in fresh plumage; greyish-brown upperparts barred white, rump and uppertail-coverts red; brown wing-coverts barred off-white, tipped white; brown flight-feathers barred whitish; uppertail brown, barred off-white.

white; whitish below, breast spotted or sometimes vaguely barred brown, smaller rather faint spots on belly; underwing whitish, spotted brown; all plumage colours fade very quickly, very pale when worn; relatively long bill proportionately broad, grey, paler base, whitish base of lower mandible; iris brown; legs greenish-grey. Female as male, but entire crown and nape with more brown. Juvenile duller. **VOICE.** Common call a grating rattle, "skree-eek-eee-eee-eee-ee-eee-eeek", often repeated; also softer "tee-tee-tee-..."; low whirring "wi-i-i-i-i-i" to "ch-ch-ch-ch" in interactions; also louder rattling series of "wi" or "wik" notes.

**Habitat.** Lightly wooded steppe and semi-desert, scattered trees in dry streambeds and wadis. Lowlands; to 1600 m in Niger.

**Food and Feeding.** Poorly known. Diet insect larvae. Forages in trees, such as *Balanites* and acacias (*Acacia*), by pecking and hammering.

**Breeding.** Breeds Jan-Feb in Senegal and Mali, Mar-May in Niger, about Oct in Chad. Nest in dead branch of acacia. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare and little-known species. Sparsely distributed throughout its range. Rare in Senegal, occurs in N at Richard Toll; no recent records from Gambia. Uncommon in Nigeria. Total population likely to be small. Research needed on its ecology and breeding biology. Present in several protected areas, e.g. Djoudj National Park (Senegal), Air et Ténéré National Park (Niger), Waza National Park (Cameroon) and Ouadi Rimé-Ouadi Achim Reserve (Chad).

**Bibliography.** Bannerman (1953), Barlow *et al.* (1997), Cave & Macdonald (1955), Cawkill (1965), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fairon (1975), Fry *et al.* (1988), Gee (1984), Giraudeau *et al.* (1988), Gore (1990), Lamarche (1980, 1988), Louette (1981b), Mackworth-Præd & Grant (1957, 1970), Morel & Morel (1990), Newby (1980, 1987), Nikolaus (1987), Savaugé & Rodwell (1998), Scholtz *et al.* (1999), Short (1980, 1985b), Short & Horne (1988b), Snow (1978), Tarboton (1997).

### 75. Speckle-breasted Woodpecker

#### *Dendropicos poecilolaemus*

French: Pic à poitrine tachetée

German: Tropfenspecht

Spanish: Pito Cuellipinto

Other common names: Uganda Spotted Woodpecker

**Taxonomy.** *Dendropicus* [sic] *poecilolaemus* Reichenow, 1893, Scanga, west of Lake Albert, Zaire. Monotypic.

**Distribution.** Extreme S Nigeria (Serti) and C Cameroon E to NW Zaire and N Congo, and S Sudan, W & C Uganda and W Kenya (Nandi and Kabarnet); probably also in intervening parts of Central African Republic and N Zaire, but confirmation required.

**Descriptive notes.** c. 15 cm; 25-30 g. Male has brown forehead to mid-crown, red hindcrown and nape, white ear-coverts and neck sides streaked brown, brown-streaked malar stripe better defined along lower edge; white chin and throat sometimes lightly spotted grey; yellow-green upperparts, sometimes faint dark barring on mantle; faint bars on rump and uppertail-coverts, which also have red tips in fresh plumage (soon wear off); brown wing-coverts spotted and tipped dull yellow; brown flight-feathers edged yellowish-green, barred yellowish-white; uppertail brown, sometimes faint dull green bars; pale

greenish-yellow underparts usually suffused grey, scattered dark spots on breast and hint of bars on flanks, variable, sometimes breast narrowly barred, broader pale grey flank bars, faint belly streaking; underwing barred brown and yellowish-white; undertail yellowish-brown; fairly long bill broad across nostrils, dark grey or brownish-grey, sometimes blue-grey, culmen and base paler; iris red, sometimes brown; legs greenish to olive or olive-grey. Female has nape black, not red, blackish barring above more distinct than on male. Juvenile greyer than adult, lacking yellow tone, has mantle indistinctly barred black, underparts greyish-white with less obvious markings, eyes brown, both sexes with red on crown, more restricted on female, black nape and rear crown sides. VOICE. Dry “che che che che”.

**Habitat.** Forest edge and clearings, especially those bordering cultivations with trees; also upland savanna with forest, and riverine forest. To 2100 m in W of range; found at 700-2100 m in E.

**Food and Feeding.** Diet comprises beetle larvae, caterpillars, ants. Occurs singly or in pairs. Forages on dead trees; often visits isolated trees, even ventures into areas of elephant grass (*Pennisetum*). Uses pecking and hammering.

**Breeding.** Season May-Sept in Zaire; Mar-Sept and Nov-Jan in Uganda. Nest excavated in tree. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Locally common. Uncommon and local in Kenya. Rather poorly known. Research needed on its breeding biology.

**Bibliography.** Bannerman (1953), Britton (1980), Brown & Britton (1980), Carroll (1988), Cave & Macdonald (1955), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fry *et al.* (1988), Germain & Cornet (1994), Green (1990), Hall (1977), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981b), Mackworth-Praed & Grant (1957, 1970), Nikolaus (1987), Pedersen (2000), Quantrell & Quantrell (1998), Short (1980, 1985b), Short & Horne (1988b), Short *et al.* (1990), Snow (1978), Stevenson & Fanshawe (2001), Tarboton (1997), Zimmerman *et al.* (1996).

76. Abyssinian Woodpecker

*Dendropicos abyssinicus*

**French:** Pic d'Abyssinie      **German:** Wacholderspecht      **Spanish:** Pito Abisinio  
**Other common names:** Gold-mantled/(Abyssinian/African) Golden-backed Woodpecker

**Taxonomy.** *Picus Abyssinicus* Stanley, 1814, Ethiopia. Sometimes regarded as forming a superspecies with *D. fuscescens*. Monotypic.

**Distribution.** Ethiopian Highlands, from upper R Anseber in Eritrea E to Harar region and S to Alata.

**Descriptive notes.** c. 16 cm; 23-26 g. Male has brown forehead and forecrown, red hindcrown and nape, brown band through ear-coverts to neck side, broad brown malar stripe; rest of face white, chin and throat streaked brown; greenish-brown mantle, back, scapulars and inner wing-coverts with broad yellowish-golden tips, occasionally some reddish-green tips, brown bases, appearing quite mottled when worn; red rump and uppertail-coverts; brown outer wing-coverts broadly tipped white; dark brown flight-feathers edged yellowish, barred white, bars broadest but duller on tertials; uppertail brown, narrowly barred white; underparts

white, tinged yellow, streaked blackish-brown, streaks broadest on breast and flanks; underwing-coverts off-white, barred and streaked brown; undertail yellowish-brown, obscurely pale-barred; longish bill fairly broad, dark grey, paler towards base; iris brown to reddish; legs lead-grey. Female has brown hindcrown merging into dark nape. Juvenile greener, less golden above, rump paler red, whiter and heavily streaked below, indication of barring on belly, both sexes with red crown, slightly smaller on female, black nape. VOICE. Not recorded.

**Habitat.** Mostly juniper (*Juniperus*) woods and *Hagenia* forest, also areas of *Euphorbia*, mostly between 1600 m and 3000 m, occasionally higher; has been found also in wooded savanna, including at slightly lower elevations. Largely separated by altitude from *D. fuscescens*.

**Food and Feeding.** Diet not recorded. Forages on trees, by probing into mosses.

**Breeding.** Season probably Dec-May. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon. Occurs in Bale Mountains National Park, Ethiopia. A little-known species; research is required to determine its ecology and breeding biology. Has probably suffered some contraction of its range in recent decades as a result of habitat destruction, as increasingly large areas of native woodland have been converted to eucalyptus (*Eucalyptus*) plantations. This species' conservation status possibly merits reassessment; research and monitoring desirable, but very difficult in the region because of nature of terrain and unstable political situation.

**Bibliography.** Ash & Gullick (1989), Cheesman & Sclater (1935), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Francis & Shirihai (1999), Fry *et al.* (1988), Mackworth-Praed & Grant (1957), Ryan (2001), Shirihai & Francis (1999), Short (1980, 1985b), Short & Horne (1988b), Smith (1957), Snow (1978), Tarboton (1997), Tilahun *et al.* (1996), Urban (1980), Urban & Brown (1971), Zinner (2001).

77. Cardinal Woodpecker

*Dendropicos fuscescens*

**French:** Pic cardinal      **German:** Kardinalspecht      **Spanish:** Pito Cardenal

**Taxonomy.** *Picus fuscescens* Vieillot, 1818, Swellendam district, Cape Province, South Africa. Sometimes regarded as forming a superspecies with *D. abyssinicus*. Races often treated as comprising three geographical groups: NE “*hemprichii* group”, also including *massaicus*: W & C “*lafresnayi* group”, also including *sharpii* and *lepidus*; and S “*fuscescens* group”, which also contains *intermedius*, *centralis* and *hartlaubii*. Races intergrade to variable extent, also interbreed, especially in E & S. Numerous other described races are all considered insufficiently differentiated to warrant recognition: *cosensis*, known from single type specimen (Senegal), is merged with *lafresnayi*, and *camerunensis* (Cameroon) with *sharpii*; *chyulu* (Chyulu Hills, in S Kenya) is synonymized with *hartlaubii*; *loandae* (N Angola to W Zaire) is synonymized with *centralis*, as are *camacupae* (Angolan plateau E to Malawi), *stresemani* (N Namibia) and *capriensis* (SW Zambia to N Botswana); *harei* (S Namibia) and *orangensis* (Orange River Basin in E South Africa) are lumped with nominate; and *transvaalensis* (S Zimbabwe and NE Transvaal), *noomei* (coastal S Mozambique and NE Natal) and *natalensis* (lowland E Transvaal and Natal) are regarded as synonyms of *intermedius*. Nine subspecies recognized.

**Subspecies and Distribution.**

*D. f. lafresnayi* Malherbe, 1849 - Senegambia E to Nigeria.  
*D. f. sharpii* Oustalet, 1879 - Cameroon and Central African Republic E to S Sudan, S to N Angola and W Zaire.  
*D. f. lepidus* (Cabanis & Heine, 1863) - E Zaire, and highlands of Ethiopia, Uganda, W & C Kenya, Rwanda and NW Tanzania.  
*D. f. massaicus* Neumann, 1900 - S Ethiopia at middle elevations, and W Kenya and C Tanzania at lower altitudes.  
*D. f. hemprichii* (Ehrenberg, 1833) - Ethiopia (lower elevations), Somalia, and N & E Kenya.  
*D. f. centralis* Neumann, 1900 - E Angola E to W Tanzania, S to N Namibia and Zambia.  
*D. f. hartlaubii* Malherbe, 1849 - from Kenya-Tanzania border S to extreme E Zambia, Malawi and C Mozambique (R Zambezi).  
*D. f. fuscescens* (Vieillot, 1818) - NC Namibia, Botswana, and most of South Africa E to S Transvaal and W Natal.  
*D. f. intermedius* Roberts, 1924 - C Mozambique (R Zambezi) S to Transvaal and Natal.

**Descriptive notes.** 14-16 cm; 20-31 g (*lepidus*), 29-37 g (*fuscescens*). Male has brownish forehead to mid-crown, red hindcrown to hindneck, broad white supercilium behind eye extending around rear of ear-coverts, buffish or white lores, off-white or grey-white cheeks and ear-coverts very finely and inconspicuously streaked dark; broad brownish-black malar stripe expanding on lower neck sides; white chin and throat sometimes finely spotted or streaked brown; upperparts dark brown with white to pale olive-white bars, rump and uppertail-coverts yellow, latter tipped light reddish; blackish-brown wing-coverts strongly spotted white or yellowish-white, flight-feathers barred whitish; uppertail brown, barred yellow-white, pale shafts; white below, often tinged yellow-buff when fresh, breast and sides broadly streaked brownish-black, lower flanks, belly and undertail-coverts more barred; underwing greyish-black, coverts white; undertail barred; entire plumage duller when worn, less olive or yellow tinge in pale areas, can appear very black and white; longish bill broad, blackish, sometimes with blue or brown tones, lower mandible paler; iris red to red-brown; legs greenish-grey to green-brown. Female differs in having darker brown forehead merging into black rear crown and nape. Juvenile duller, greyer, less contrastingly patterned, has eyes brown or grey-brown, both sexes with red patch in centre of crown, somewhat smaller on female, black nape and hindneck. Races vary mostly in upperpart coloration and degree of barring, less so in size, W & C group of races small, green and less barred above, NE group smallest and palest, S group biggest and most barred: *lafresnayi* is green above with obscure bars, yellowish below with fine dark streaks, female has darker face; *sharpii* similar, but streaks below broader; *lepidus* is larger than last two, unbarred above (female somewhat more barred in Kenyan highlands), pale below with streaks very narrow; *massaicus* is fully barred above, tinged yellow above and below, but more contrasted than previous, birds at higher elevations larger and darker; *hemprichii* is slightly smaller than previous, paler, has narrower dark barring above; *centralis* is browner, less black, above than nominate, barring more yellow, yellow below with streaks finer, less barring on belly; *hartlaubii* is smaller, especially coastal populations, than previous, bars above olive-brown and pale yellowish-olive, yellow with olive-brown streaks below; *intermedius* has bars above more olive-black and yellowish-white, streaks below narrower. VOICE. Shrill chittering “kweek-cek-cek-ik-ik” by both sexes; “creek, creek, creek” and “kweek-a, kweek-a” in aggression; repeated “kee-kee-kee-kee” from nestlings. Drumming rapid, not very loud.

**Habitat.** Variety of open and dense woodland, wooded grassland and bushland; absent only from moist mountain forest. Inhabits riparian fringing forest, edges of lowland forest, and montane forest in highlands (where drier); occurs in, for example, *Euphorbia-Acacia* woodland in Ethiopia, and *Brachystegia* woodland, especially if not disturbed by human activities, in Zambia. Also in arid scrub (*hemprichii*). Also found in mangroves in W Africa, and in plantations, orchards, parks and gardens. Race *lepidus* more an inhabitant of forest than are other races. Avoids thick forest and treeless areas in Somalia. From lowlands to middle and higher elevations; common at c. 1800 m in Ethiopia; to 1800 m in Zimbabwe, to 2100 m in Malawi, to 2600 m in E Africa, even to 3500 m in Zaire.

**Food and Feeding.** Insects and their larvae, particularly beetles; also caterpillars. Termites (Isoptera), grasshoppers (Orthoptera) and fruits also recorded eaten. Usually hunts singly or in pairs; commonly joins mixed feeding flocks. Moves quickly through habitat, giving frequent contact calls. Forages mostly at lower levels, but also at higher levels in outer canopy, and down to ground; in trees, bushes, creepers, preferring smaller branches and twigs; hangs from smallest twigs; visits reeds and even dry stalks of cultivated maize, also seed pods (e.g. of *Swartzia madagascariensis*). Main techniques are pecking and probing, also hammering. Sometimes accompanied by *Campephaga abingoni*, which pecks less and does not exploit very small twigs. Subordinate to *D. namaquus* when the two meet.

**Breeding.** Season about Feb-Jul in W Africa, nest in Dec in Sierra Leone; Jun-Nov in Angola; nest with chicks in mid-late Mar in N Somalia; breeds throughout year in E Africa, with wide local variation, no clear association with rainy or dry seasons: Apr-Jan, but mostly Aug-Oct, in S Africa. Nest-hole excavated by both sexes, duration c. 2 weeks, at 1.5-18 m in dead trunk or branch of tree; cavity depth 15 cm or more. Clutch 2 or 3 eggs, rarely 1 or 5; incubation by both parents, from first egg, male sometimes feeding female at nest, incubation period 10-13 days; both also feed chicks, nestling period c. 27 days; fledged brood divided between parents, sex for sex, accompanied by them for 8-10 weeks. Nests parasitized by Scaly-throated Honeyguide (*Indicator variegatus*), probably also by Greater Honeyguide (*I. indicator*).

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common and widespread throughout almost entire range; Africa's most widespread woodpecker, occurring in most of continent S of Sahara; commonest woodpecker in E & S Africa, also in many other areas. Occurs in numerous national parks, e.g. Comoé (Ivory Coast), Bénoué (Cameroon), Awash (Ethiopia), Murchison Falls (Uganda), Amboseli and Tsavos (Kenya), Serengeti and Mikumi (Tanzania), and Kruger (South Africa).

**Bibliography.** Allport *et al.* (1989), Archer & Godman (1937-1961), Ash & Miskell (1998), Attwell (1952), Bannerman (1953), Barlow *et al.* (1997), Benson & Benson (1977), Benson *et al.* (1971), Brown (1993), Cave & Macdonald (1955), Cheke & Walsh (1996), Christy & Clarke (1994), Dean (1974b, 2000), Dowsett (1990), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Evans *et al.* (1994), Friedmann (1930a), Fry *et al.* (1988), Germain & Cornet (1994), Ginn *et al.* (1989), Gore (1990), Graaf (1992), Greig-Smith (1976), Harrison *et al.* (1997), King (2000), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), Nikolaus (2000), Pakenham (1979), Penry (1994), Pinto (1983), Ripley & Heinrich (1969), Roberts (1924), Sauvage & Rodwell (1998), Short (1980, 1985b), Short & Horne (1988b), Snow (1978), Spottiswoode (1994), Tarboton (1980, 1997, 2001), Tarboton *et al.* (1987), Underhill & Underhill (1992b), Vernon (1980), Willows (1989), Wilson & Wilson (1992), Zimmerman (1972), Zimmerman *et al.* (1996).

78. Melancholy Woodpecker

*Dendropicos lugubris*

French: Pic à raies noires      German: Düsterspecht      Spanish: Pito Lúgubre

**Taxonomy.** *Dendropicos lugubris* Hartlaub, 1857, Aguapim, Ghana. Forms a superspecies with *D. gabonensis*; sometimes treated as conspecific, a view supported by the fact that race *reichenowi* of latter in Nigeria and Cameroon is somewhat intermediate between present species and nominate *D. g. gabonensis*; indeed, *reichenowi* was formerly considered to belong instead to present species. Monotypic.

**Distribution.** Sierra Leone to SE Ghana, S Nigeria and SW Cameroon.

**Descriptive notes.** c. 17-18 cm. Male has olive-brown forehead and crown, red nape, thin white supercilium, brown ear-coverts, white neck sides and broad white cheekstripe, broad brown malar stripe; white chin and throat, often with some dark spots or streaks; entire upperparts bronze-green, occasionally paler feather tips forming very indistinct bars; brown flight-feathers edged greenish-bronze, barred or spotted white on inner webs; uppertail black; underparts pale greenish-yellow, feathers with broad dark brown centres, streaks continuing to vent; underwing pale yellowish-white, spotted brown; undertail grey-black; shortish bill

fairly broad across nostrils, greyish to blackish, paler base and lower mandible; iris red to red-brown; legs greenish, tinged brown, olive or yellow. Distinguished from *D. gabonensis* by head pattern, broader dark markings below, more bronzy upperparts, blacker tail. Female has nape blackish, not red. Juvenile duller, lacking bronze tone above, has eyes brown, both sexes with black nape, small red patch on hindcrown. VOICE. Common call a drawn-out buzzing note, as that of *D. gabonensis*; also fast rattle, "bddd dddd dddd d-it" or "br-r-r-r-r-r-ip"; also "rrek-rrek-rrek-rak-rak" and low "pit" or "pa-bit" during encounters. Drums fairly loudly.

**Habitat.** Open forest, second growth, forest edge, clearings, also *Gmelina* woodland; also gallery forest, swamp-forest, exotic plantations and gardens in W Africa. From lowlands to c. 1200 m; ascends above 1300 m in Liberia, possibly also elsewhere.

**Food and Feeding.** Insects, including ants, beetle larvae. Usually in pairs or family parties; often joins mixed-species foraging flocks. Forages mainly in canopy, sometimes descending to understorey; prefers smaller horizontal branches. Probes, gleans; appears to use pecking and hammering to only minimal extent.

**Breeding.** Oct-Mar in Sierra Leone; nestlings found in Mar and Apr in Liberia. Nest-hole at 15-30 m in dead tree branch or dead part of trunk. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rather uncommon throughout relatively small range. Common in Sierra Leone. Locally not uncommon to common in Liberia, where estimated 50,000 pairs. Occurs in Gola Forests Reserves (Sierra Leone) and Tai Forest National Park and IIRSDA Research Station (Ivory Coast). Not a well-known species; further research on its ecology and breeding biology is desirable.

**Bibliography.** Allport *et al.* (1989), Bannerman (1953), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Gartshore *et al.* (1995), Gatter (1997), Grimes (1987), Mackworth-Præd & Grant (1970), Rand (1951), Salewski (2000), Short (1980), Tarboton (1997), Thiollay (1985a), Waltert *et al.* (1999), Wheatley (1995).

79. Gabon Woodpecker

*Dendropicos gabonensis*

French: Pic du Gabon      German: Gabunspecht      Spanish: Pito del Gabón

**Taxonomy.** *Dendrobates Gabonensis* J. Verreaux and E. Verreaux, 1851, Gabon. Forms a superspecies with *D. lugubris*; sometimes treated as conspecific, a view supported by the fact that race *reichenowi* is somewhat intermediate between that species and nominate *gabonensis*; indeed, *reichenowi* was formerly considered to belong instead to *D. lugubris*. Two subspecies recognized.

**Subspecies and Distribution.**

*D. g. reichenowi* Sjöstedt, 1893 - S Nigeria and SW Cameroon.  
*D. g. gabonensis* (J. Verreaux & E. Verreaux, 1851) - S Cameroon (except SW) and SW Central African Republic S to N Angola (Cabinda), and E across N & C Zaire (E to W slope of Ruwenzori, S to W Kasai) to extreme W Uganda.

**Descriptive notes.** c. 16-17 cm; 24-30 g. Male has olive-brown forehead and forecrown, rarely with pale streaks, red hindcrown and nape, indistinct dark-streaked white supercilium, heavily brown-streaked ear-coverts bordered below by dark-streaked buffish cheekstripe, thin brown malar stripe; buffish-green neck sides streaked dark; whitish chin and throat spotted or streaked brown; entire upperparts green, mantle and rump rarely with faint barring; brown flight-feathers edged green, bars on inner webs; uppertail olive, edged greenish-brown, tipped dark, occasionally hint of pale green bars; pale yellowish below, breast with

fairly narrow short spot-like streaks, becoming broader spots on lower underparts, bars on lower flanks; underwing yellow-white, spotted brown; undertail yellow-green; rather short bill fairly broad across nostrils, dark grey to blackish, paler base and lower mandible; iris red to red-brown; legs brown-green to yellow-green. Differs from *D. lugubris* in greener upperparts, greener tail, dark-patterned neck sides, narrower markings below. Female lacks red on head, has blackish-brown

crown and nape. Juvenile duller, above greener, with brown eyes, both sexes with red patch on central crown, black nape. Race *reichenowi* differs from nominate in brighter coloration, stronger brown malar, darker tail, broader streaks below, male with slightly less red on hindcrown and female generally darker about crown. VOICE. Common call a single buzzing "zh-dzeeep", or fast repeated "dzhaah, dzhaah, dzheep" and variations.

**Habitat.** Inhabits forest edge, tall second growth, and edges of cultivation, generally at altitudes below 1400 m; apparently avoids open savanna-type habitats and riverine forest, as well as denser woodland.

**Food and Feeding.** Insects, mainly ants, and insect larvae, especially wood-boring ones. Mostly in pairs. Feeds in canopy and understorey. Forages by probing and gleaning; also pecks, and prises off pieces of bark or wood.

**Breeding.** Specimens with slightly enlarged gonads in Oct, and male excavating nest-hole in mid-Oct, in Nigeria; birds in breeding condition in Sept-Oct in Cameroon and Zaire; Jun in Uganda. Nest-hole in tree; no other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally common. Uncommon in Nigeria; locally quite common in Gabon. Present in several protected areas, e.g. Korup National Park (Cameroon) and La Lopé National Park (Gabon). Poorly known; further study required to determine its exact distribution, as well as its ecology and breeding habits.

**Bibliography.** Bannerman (1953), Bowden (2001), Britton (1980), Christy & Clarke (1994), Dean (2000), Dowsett (1989b), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1999, 2000), Elgood *et al.* (1994), Fry *et al.* (1988), Lippens & Wille (1976), Louette (1981b), Mackworth-Præd & Grant (1970), Sargeant (1993), Short (1980, 1985b), Snow (1978), Stevenson & Fanshawe (2001), Tarboton (1997), Thiollay (1985b).

80. Stierling's Woodpecker

*Dendropicos stierlingi*

French: Pic de Stierling      German: Stierlingspecht      Spanish: Pito de Stierling

**Taxonomy.** *Dendropicos stierlingi* Reichenow, 1901, Songea, Tanzania. Relationships uncertain. Monotypic.

**Distribution.** S Tanzania (Songea, Lindi), N Mozambique and adjacent SW Malawi; possibly also E Zambia.

**Descriptive notes.** c. 17-18 cm; 25-31 g. Male has blackish-brown forehead and forecrown, in fresh plumage with narrow pale feather edges, red hindcrown and nape, white neck side and face with blackish-brown ear-coverts, broad blackish-brown malar stripe expanding on neck side and down to breast side; white chin and upper throat; black hindneck and uppermost mantle; rest of upperparts olive-brown, slightly paler tips when fresh, uppertail-coverts faintly pale-barred, occasionally reddish tips in fresh plumage; brown flight-feathers and outer wing-coverts edged olive, remiges barred white on inner webs; uppertail brown, tip yellow;

lower throat chequered white and dark brown, rest of underparts scaly-looking, white with dark brown bars and shaft streaks; underwing white, spotted brown; undertail yellowish-brown; long bill fairly broad, slate-grey, paler base of lower mandible; iris red to red-brown; legs olive to grey-green. Female lacks red on head, has faintly pale-streaked brown crown, blacker nape. Juvenile duller, markings below more irregular, has brown eyes, both sexes with red in centre of crown. VOICE. Common call somewhat wavering "pi-di-di, da-da-di, da-da-da-da, da-da", as territorial and long-distance communication; also soft single or repeated "pik" notes, sometimes in short bursts; "bddd" notes in aggression; irregular "weep" series also recorded. Drumming loud, rapid, c. 5 rolls per minute.

**Habitat.** Inhabits rich miombo (*Brachystegia*) woodland, from lowlands up to 1500 m.

**Food and Feeding.** Diet includes insects and their larvae; occasionally centipedes (Chilopoda). Occurs singly or in pairs; associates loosely with mixed-species flocks. Forages in middle to upper levels of forest; may spend considerable time at one site. Investigates large to medium-sized branches, less frequently twigs. Main foraging technique consists of powerful pecking; can excavate deeply into bark; also probes in bark. During rainy season hawks alate termites (Isoptera), in rather clumsy fashion.

**Breeding.** Season probably Jul-Oct; nestlings in Aug in Malawi, juvenile observed in Nov in Tanzania; juvenile also reported in Mar in NW Mozambique. Nest-hole in tree; nest in Malawi contained 2 chicks. No other data.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Not uncommon in most parts of small range, but rather localized. A generally little-known species, with few published observations. Exact status requires further investigation. Information required also on its breeding biology.

**Bibliography.** Benson & Benson (1977), Britton (1980), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Johnston-Stewart (1988), Johnston-Stewart & Heigham (1982), Mackworth-Præd & Grant (1957, 1962), Newman *et al.* (1992), Short (1980, 1985b), Short & Horne (1981), Short *et al.* (1990), Snow (1978), Stevenson & Fanshawe (2001), Tarboton (1997).

81. Bearded Woodpecker

*Dendropicos namaquus*

French: Pic barbu      German: Namaspecht      Spanish: Pito Namaqua

**Taxonomy.** *Picus Namaquus* A. A. H. Lichtenstein, 1793, Damaraland, Namibia. Often placed in a separate genus *Thripas* along with *D. pyrrhogaster* and *D. xantholophus*. Races known to intergrade. Proposed races *saturatus* (W Central African Republic) and *decipiens* (SW Uganda and S Kenya S to C Tanzania) inseparable from nominate. Three subspecies currently recognized.

**Subspecies and Distribution.**

*D. n. namaquus* (A. A. H. Lichtenstein, 1793) - W Central African Republic E to S Sudan, Uganda and W & S Kenya, and from W & S Angola across to SE Zaire and Tanzania, S to W & C Namibia, Botswana, N South Africa and N & C Mozambique.

*D. n. schoensis* (Rüppell, 1842) - Ethiopia, NW & S Somalia and N Kenya.

*D. n. coalescens* (Clancey, 1958) - C & S Mozambique and E South Africa.

**Descriptive notes.** 24-27 cm; 61-89 g. Male has black forehead and forecrown with small white spots, red hindcrown sometimes with yellowish at fore edge, black nape and hindneck; whitish lores, short black stripe in front of eye; broad white supercilium curving behind black ear-coverts, broad white band from bill base backwards, dark streaks on neck side; black malar stripe broadening on throat side; white chin and throat sometimes with few dark streaks or bars; uppermost mantle black, rest of upperparts yellowish-brown with thin pale bars, rump paler, grey-brown uppertail-coverts tipped yellow (or reddish); brown wing-coverts pale-fringed, spotted white; brown flight-feathers heavily barred whitish on both webs; uppertail brownish, barred whitish, prominent yellow shafts; underparts olive-grey, browner in lower parts, all barred whitish; underwing barred blackish and grey-white; undertail dull yellowish-brown, barred paler; very long bill broad, grey-black, paler base of lower mandible; iris reddish-brown or red; legs grey, often tinged olive or green. Female resembles male, but bill slightly shorter, no red on head. Juvenile tinged green and more diffusely barred above than adult, has eyes greyer or browner, both sexes with red crown patch mixed with black and usually heavily white-spotted, red sometimes extending to nape. Race *schoensis* is shorter-winged than nominate, browner above, sometimes with black bar between rear ear-coverts and malar, markings below more as spots or arrowheads; *coalescens* is darker, olive-brown with broken barring above, often red-tipped tail-coverts, darker grey below, bars on breast incomplete. **VOICE.** Common call an accelerating rattle series of 5-15 "wik" notes, similar to song of Grey-headed Kingfisher (*Halcyon leucocephala*); chattering "wickwickwickwick-wick-wick" series; also "chip chip chip"; loud nasal scream also recorded; piping cackle by nestlings. Drums loudly, each roll followed by 4 regular taps, "ttrrrrr-tap-tap-tap", longer rolls than those of *D. pyrrhogaster*.

**Habitat.** Open woodland with large trees. Favours wooded dry savanna, especially with mopane (*Colophospermum*), also edges of riparian fringing forest, and taller *Acacia* on alluvium soils; occurs regularly in miombo (*Brachystegia*) woodland, *Euphorbia-Acacia* woodland, and bushland. Least numerous in richer woodland, and avoids moist mountain slopes. In Somalia, associated with tall trees bordering seasonal rivers and groups of larger trees in grasslands in N, and lowland riverine forest in more open areas in S. Ranges from sea-level to at least 2600 m, locally to 3000 m; to 1800 m in Ethiopia; mostly at 900-1350 m in N Somalia.

**Food and Feeding.** Diet consists of insects and their larvae, particularly wood-boring beetles and their larvae, caterpillars and ants; also takes spiders. Will pursue geckos or small lizards, and then feeds them to young. Seen mostly singly and in pairs. Forages at all levels, from ground up to canopy. Foraging ranges large, and may cover lengthy distances between foraging localities; spends long periods at a single site. Forages on dead trees, preferentially larger ones, often high on trunk, and on larger and smaller branches. Females apparently prefer smaller trees and smaller branches than those exploited by males. Excavates with vigorous pecking and hammering; also probes, and gleans to some extent.

**Breeding.** Probably Jan-Oct in Angola; Apr/May-Jun in Ethiopia; laying recorded in late Sept in N Somalia; Apr-Oct in Kenya, Jun-Nov in Tanzania, Jun-Jul in Malawi, and Jun-Dec in Zimbabwe and Zambia; May-Nov in South Africa, mostly May-Aug. Nest-hole excavated at 2-20 m in dead part of tree, rather large entrance 7.5 cm high, 5.5 cm wide; may be reused several times; territory large. Clutch 2-4 eggs, usually 3; both parents incubate, period 13 days; both provide equally for chicks, nestling period c. 27 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Widespread and fairly common, but often very local; seldom numerous. Not uncommon in Angola; fairly common in Ethiopia; uncommon in Somalia; uncommon to fairly common and local in Kenya; locally common in Namibia. Occurs in numerous protected areas, e.g. Awash National Park (Ethiopia), Lake Nakuru and Samburu National Parks (Kenya), Serengeti and Mikumi National Parks (Tanzania), Etosha National Park (Namibia) and Mkuji Game Reserve (South Africa). Apparent scarcity in some areas is possibly due to the fact that it occupies large home ranges.

**Bibliography.** Ash & Miskell (1983, 1988), Benson & Benson (1977), Benson *et al.* (1971), Brown, C.J. (1993), Brown, L.H. & Britton (1980), Carroll (1988), Clancey (1958b, 1989a), Davey (1994), Dean (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Farnsworth *et al.* (2000), Fry *et al.* (1988), Ginn *et al.* (1989), Harrison *et al.* (1997), Hines (1995), Irwin (1981), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Præd & Grant (1957, 1962), Maclean (1993), Nikolaus (1987), Oatley (2001), Penry (1994), Pinto (1983), Pringle (1991), Short (1980, 1985b), Short & Horne (1988b), Short *et al.* (1990), Skead (1967), Snow (1978), Tarboton (1970, 1997, 2001), Tarboton *et al.* (1987), Urban & Brown (1971), Zimmerman *et al.* (1996).

**82. Fire-bellied Woodpecker***Dendropicos pyrrhogaster*

**French:** Pic à ventre de feu

**German:** Rotbauchspecht

**Spanish:** Pito Ventrirrojo

**Taxonomy.** *Picus* (*Chloropicus*) *Pyrrhogaster* Malherbe, 1845, South Africa; error = Sierra Leone. Often placed in a separate genus *Thripias* along with *D. namaquus* and *D. xantholophus*. Forms a superspecies with latter. Monotypic.

**Distribution.** Sierra Leone and S Guinea E to S Nigeria (Niger Delta) and SW Cameroon.

**Descriptive notes.** c. 24 cm; 63-74 g. Male has brownish-black forehead, red crown to nape, rarely buffish-yellow in crown centre, black feather bases more obvious in worn plumage; white lores, black ear-coverts curving down at rear; neck side and rest of face white, with black malar stripe continuing to breast side; white chin and throat; bronze-green mantle, scapulars and back, often some indistinct bars and red tips to feathers when fresh; red rump and uppertail-coverts with black feather bases; brownish-bronze-green wing-coverts narrowly fringed paler, few pale spots on medians; brown flight-feathers narrowly edged paler, inner webs with broad white bars, outerwebs with narrow yellow-white bars; uppertail olive-black; broad red band centrally from breast to vent, broad black streaks on upper breast sides, rest of underparts off-white with heavy arrowhead barring; underwing whitish; undertail dull yellow-green; long bill broad, dark grey,

paler lower mandible; iris brown to red; legs green to grey-green. Female has slightly shorter bill, relatively longer tail than male, no red on head. Juvenile duller, less bronzy above, black areas of plumage browner, red areas duller and less extensive, eyes brown, both sexes with red on crown, on female red mixed with brown. **Voice.** Sharp "wip"; "wip-wi-di-di-di-dit" as long-distance call. Drums often in loud accelerating rolls weakening towards end, rolls shorter than those of *D. namaquus* and *D. xantholophus*.

**Habitat.** Inhabits primary and secondary forest in lowlands and on lower slopes. Prefers the vicinity of large trees, and not uncommon at edges and clearings with fire-killed trees; also visits tall trees, often dead ones, along rivers or in isolated forest patches, and forest-grassland mosaic.

**Food and Feeding.** Diet consists of insects, larvae of beetles and white ants. Often forages in pairs; will join mixed-species flocks. Forages in upper levels of trees, at 10-40 m; may descend to fallen logs. Inspects branches mostly of 5-30 cm in diameter. Excavates in search of food by means of pecking and hammering.

**Breeding.** Nov-Feb in Sierra Leone; Nov-Mar, also nestlings once in Jul, in Liberia; breeds Oct-Mar, possibly from Aug/Sept, in Nigeria. Nest-hole excavated at 20-30 m or higher in tree, often in dead branch. No information on clutch size and incubation and nestling periods.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally common. Not uncommon in Sierra Leone; not uncommon in Liberia, where densities of more than 3 pairs/km<sup>2</sup>, estimated population 60,000 pairs; common in Nigeria. Benefits from practice of forest clearance whereby largest trees are left standing, to die naturally; this species' preference for big trees means that resultant habitat provides ideal conditions, although only temporarily. Present in several protected areas, e.g. Gola Forests Reserves (Sierra Leone), Tai Forest National Park (Ivory Coast) and Korup National Park (Cameroon).

**Bibliography.** Allport *et al.* (1989), Ash & Sharland (1986), Bannerman (1953), Cheke & Walsh (1996), Cheke *et al.* (1986), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Farmer (1979), Fry *et al.* (1988), Gartshore *et al.* (1995), Gatter (1988, 1997), Grimes (1987), Hopkins (1998), Louette (1981b), Mackworth-Præd & Grant (1970), Ntiemoa-Baidu, Asamoah *et al.* (2000), Ntiemoa-Baidu, Owusu *et al.* (2000), Rand (1951), Salewski (2000), Short (1980, 1985b), Short & Horne (1988b), Snow (1978), Sørensen *et al.* (1996), Thiollay (1985a, 1985b), Waltert *et al.* (1999).

**83. Golden-crowned Woodpecker***Dendropicos xantholophus*

**French:** Pic à couronne d'or

**German:** Scheitelfleckspecht

**Spanish:** Pito Coronado

**Other common names:** Yellow-crested Woodpecker

**Taxonomy.** *Dendropicus* [sic] *xantholophus* Hargitt, 1883, Gabon.

Often placed in a separate genus *Thripias* along with *D. namaquus* and *D. pyrrhogaster*. Forms a superspecies with latter. Monotypic.

**Distribution.** SW Cameroon E to S Sudan, W & C Uganda and extreme W Kenya, and S to NW Angola and SW & SC Zaire; unconfirmed sight records from Nigeria thought to be unreliable.

**Descriptive notes.** c. 25 cm; 50-73 g. Male has brown forehead merging into blackish crown, crown feathers with few white speckles, broad yellow tips, black nape and hindneck; white lores, broad black band from just before eye through ear-coverts and down to side of neck; rest of neck and face white, black malar stripe broadening on side of throat; white chin and throat, lower throat tinged olive and with row of black spots; uppermost mantle black, rest of upperparts olive-brown, mantle sometimes with few faint paler bars, rump and uppertail-coverts with narrow yellow tips; olive wing-coverts with

variable number of pale tips and subterminal spots; brownish-black flight-feathers narrowly edged and tipped green, barred white on both webs; uppertail black; greenish-olive below, breast with white spots, flanks to belly and undertail-coverts barred whitish; underwing off-white; undertail dull blackish; bill long and broad, dark grey to black, paler cutting edges, paler lower mandible; iris red to brown; legs green to olive or brownish. Female is slightly shorter-billed than male, has no yellow on crown. Juvenile duller and greener above, greyer and more barred below, has eyes less red, both sexes with hindcrown feathers tipped yellow, less on female. **Voice.** Single "dit" and "dit-it" notes to fast bursts of purring "ddditrrrrrr" and grating "grrrrrr"; also very fast "dddit, graa" and "a-wik a-wik" during encounters. Both sexes drum, rolls accelerating, weakening towards end, longer than rolls of *D. pyrrhogaster*.

**Habitat.** Mainly areas with large trees in lowland forest, forest edge, also in nearby thick secondary growth, occasionally densely wooded areas and cultivated plantations (e.g. coffee, cocoa); visits isolated large trees outside forest. Lowlands to c. 1700 m; to 2150 m in E.

**Food and Feeding.** Diet largely of wood-boring beetles and their larvae; also takes other insects (ants), and spiders. Mostly singly or in pairs. Forages in middle and upper storeys; pecks strongly and hammers or removes bark. Also takes prey on the wing.

**Breeding.** Probably Oct-Mar in Cameroon, and Jan-Apr and Sept elsewhere in W; Jun-Sept in Angola; Sept-Mar in Uganda and Kenya. Nest-hole excavated by both sexes, at up to 17 m in dead tree or dead section of tree. No other information available.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common forest woodpecker. Considered common in Angola; uncommon in Kenya. Rather poorly known, but appears to be under no threat. Present in several protected areas, e.g. Korup and Mount Kupe National Parks (Cameroon), Kakmenga Nature Reserve (Kenya) and Nyungwe Forest Reserve (Rwanda).

**Bibliography.** Bannerman (1953), Bowden (2001), Britton (1980), Brown & Britton (1980), Carroll (1988), Cave & Macdonald (1955), Christy & Clarke (1994), Dean (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (2000), Elgood *et al.* (1994), Fry *et al.* (1988), Lippens & Wille (1976), Louette (1981b), Mackworth-Præd & Grant (1957, 1962), Nikolaus (1987), Pedersen (2000), Pinto

(1983), Short (1971b, 1971d, 1980, 1985b), Short & Horne (1988b), Short *et al.* (1990), Snow (1978), Stevenson & Fanshawe (2001), Tarboton (1997), Thiollay (1985b), Zimmerman (1972), Zimmerman *et al.* (1996).

## 84. Elliot's Woodpecker

### *Dendropicos elliotii*

**French:** Pic d'Elliot

**German:** Elliotspecht

**Spanish:** Pito de Elliot

**Other common names:** Johnston's Woodpecker (*johnstoni*)

**Taxonomy.** *Polipicus Elliotii* Cassin, 1863, Muni River, Gabon.

Sometimes placed in a separate genus *Mesopicus* along with *D. goertae*, *D. spodocephalus* and *D. griseocephalus*; in past, sometimes separated alone in genus *Polipicus*. Race *johnstoni* regarded by some authors as a separate species, but interbreeds with nominate in Cameroon; apparent intermediates between these two races on Mt Kupé have been separated by some authors as race *kupeensis* but probably best considered a hybrid population. Other named races are *schultzei* (Bioko I) and *sordidatus* (Oku district, in Bamenda Highlands of Cameroon), both of which seem indistinguishable from *johnstoni*. Angolan birds formerly split as race *gabela* or *angolensis* but they differ from nominate barely, if at all. Two subspecies currently recognized.

#### Subspecies and Distribution.

*D. e. johnstoni* (Shelley, 1887) - highlands of SE Nigeria, SW Cameroon and Bioko I.

*D. e. elliotii* (Cassin, 1863) - lowland SW Cameroon and SW Central African Republic discontinuously to Gabon and W Angola (Cuanza Norte S to Benguela), and E across W, SC & NE Zaïre to SW & E Uganda (Kibale S to Bwindi Forest, also Mt Elgon).

**Descriptive notes.** c. 20-22 cm; 32-40 g. Male has black forehead and forecrown, red hind-crown and nape, reddish-buff lores; crown sides and rest of head buff, rear ear-coverts and neck sides tinged greenish, very thin dark malar line; white chin and throat narrowly streaked olive; entire upperparts plain green with bronze or brownish tinge; brown flight-feathers broadly edged bronzy-green on outer webs, white on inner webs; uppertail brown, feathers edged green, outer rectrices occasionally barred buff at base; pale yellowish to yellow-brown below with broadly brown or olive streaks, often becoming bars on flanks and belly; underwing

yellowish-white; undertail yellow-brown; bill longish, broad, greyish to black, often tipped yellowish, paler lower mandible; iris red-brown to red; legs grey or green, tinged olive or brown. Female has forehead to nape entirely black. Juvenile duller overall, more streaked below, with browner eyes, male with red on crown, female red on rear crown. Race *johnstoni* has greenish-yellow underparts with streaking very fine and sparse, or even lacking. VOICE. Shrii "bwe-bwe" notes and series reported; voice apparently similar to that of *D. goertae*. Weak drumrolls.

**Habitat.** Dense primary forest, also secondary forest with tall trees. In moist, gloomy, mossy montane forest at up to 2320 m in NE of range; elsewhere, nominate race found from upland areas down to lowlands. Race *johnstoni* restricted to montane areas.

**Food and Feeding.** Larvae of beetles, also other insects. Occurs singly or in pairs; joins mixed-species flocks, occasionally with other woodpecker species. Forages at all levels of forest, including understorey. Moves rapidly, not staying for long at a single site. Pecks powerfully, and probes into epiphytes (mosses) on branches and on very large leaves.

**Breeding.** Birds in breeding condition in Sept in Angola, in Oct-Nov in Cameroon; young birds seen in Dec and Jan on Bioko. One nest-hole in Cameroon was 8 m up a tree. No further information available.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally uncommon. Race *johnstoni* not uncommon throughout range, in Nigeria and Cameroon and also on Bioko. Nominative is uncommon in Angola; uncommon to rare in Uganda. Within its range species has a very patchy distribution; range may perhaps be more extensive than currently known. Research needed to determine details of this species' breeding habits and biology. Occurs in several protected areas, e.g. Gashaka-Gumti Reserve (Nigeria), Korup and Mount Kupé National Parks (Cameroon), Impenetrable Forest and Kibale Forest National Parks (Uganda), Nyungwe Forest Reserve (Rwanda) and Kibira National Park (Burundi).

**Bibliography.** Ash *et al.* (1989), Bannerman (1953), Bowden (2001), Britton (1980), Carroll (1988), Dean (2000), Demeijer *et al.* (2000), Dowsett (1989a, 1989b, 1990), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1998, 1999, 2000), Elgood *et al.* (1994), Foto (2001), Fry *et al.* (1988), Green (1990), Larison *et al.* (2000), Lippens & Wille (1976), Louette (1981b), Mackworth-Præd & Grant (1957, 1962, 1970), Pedersen (2000), Pérez del Val (1996), Pérez del Val *et al.* (1994), Pinto (1983), Short (1980, 1985b), Short *et al.* (1990), Snow (1978), Stevenson & Fanshawe (2001), Tarboton (1997).

## 85. Grey Woodpecker

### *Dendropicos goertae*

**French:** Pic goertan

**German:** Graubrustspecht

**Spanish:** Pito Gris Occidental

**Other common names:** African Grey Woodpecker

**Taxonomy.** *Picus Goertae* P. L. S. Müller, 1776, Senegal.

Often placed with *D. spodocephalus* and *D. griseocephalus* in a separate genus *Mesopicus*, sometimes also including *D. elliotii*; forms a superspecies with the first two, hybridizing with them where ranges meet; often treated as conspecific with *D. spodocephalus*. Races intergrade. Proposed races *agmen* (tree-savanna belt from Gambia S to Liberia and across to EC Sudan), *centralis* (savanna from Cameroon to SW Sudan and W Kenya) and *oreites* (highlands of C Cameroon) all considered inseparable from nominate. Four subspecies currently recognized.

#### Subspecies and Distribution.

*D. g. koenigi* (Neumann, 1903) - Sahel zone from EC Mali E to W & S Sudan.

*D. g. goertae* (P. L. S. Müller, 1776) - SW Mauritania and Senegambia E to S Sudan and W & C Kenya, and S to NE Zaïre, Rwanda and NW Tanzania.

*D. g. abessinicus* (Reichenow, 1900) - E Sudan and N & W Ethiopia.

*D. g. meridionalis* Louette & Prigogine, 1982 - S Gabon to NW Angola (Cabinda, possibly S to Malanje), and SC Zaïre.

**Descriptive notes.** c. 20 cm; 40-52-5 g. Male has grey forehead and forecrown, red hindcrown and nape sometimes with grey feather bases showing on hindcrown; rest of head grey, on ear-

coverts sometimes darker, hindneck and sides of neck often tinged buffish to olive, obscure whitish supercilium behind eye, faint whitish malar stripe extending to lores and base of forehead; pale grey chin and throat; upperparts bronze-green to olive-green or brownish-green, red rump and uppertail-coverts; wing-coverts edged and tipped paler, hint of pale bars; brown flight-feathers barred pale, bars strongest on inner webs; uppertail brown, pale bars not quite meeting in centre; pale grey below, normally faintly tinged pale yellow, flanks with variable but usually weak white and yellowish-white bars, belly with small

yellow or orange-yellow central patch (rarely mixed with red); underwing barred black and white; undertail brown, obscurely barred pale, suffused yellow; longish bill straight, broad, slaty-grey to black, paler lower mandible; iris red to brown; legs greenish-grey, suffused chalky, with whitish joints. Distinguished from *D. spodocephalus* mainly by much smaller orange, not red, belly patch, more barred wings and tail; from *D. griseocephalus* also by paler coloration. Female has slightly shorter bill than male, no red on head. Juvenile duller above than adult, lacking bronze tinge, has red of rump paler, more obvious pale facial markings, grey-brown eyes, more barring below, smaller paler belly patch, both sexes with red in crown centre, more extensive on male. Race *koenigi* is noticeably paler than nominate, has pale bars and spots on lower back and wings, somewhat stronger pale facial markings, yellow belly patch small but more often lacking; *abessinicus* has pale supercilium, whiter malar, darker face, red belly patch; *meridionalis* resembles nominate, but browner above, no yellowish tinge below. VOICE. Series of 20-30 "wik" notes as long-distance call; irregular series of "week" or "weeka" during interactions; also "pew" and "pit-it". Drums rarely.

**Habitat.** Inhabits woodland, wooded grassland and pasture, riverine woodland, thickets with larger trees, forest edges, gardens, cultivations with trees; shows strong liking for palms. Also found in mangroves in W of range.

**Food and Feeding.** Ants, termites (Isoptera), beetle larvae, other insects; also observed hunting crabs among aerial roots of mangroves, and taking nuts of oil palm (*Elaeis guineensis*). Seen in pairs or family groups. Forages mostly at medium levels, on live and dead trees, on larger branches and trunks; also descends to ground. Moves rapidly. Main technique pecking, excavating for prey. Some insects taken on the wing.

**Breeding.** Dec-Jun in W of range, from Oct in Sierra Leone, Jan-Mar in Nigeria, Dec-Feb and Jul-Sept in Zaïre, and Feb-Jul and Sept-Nov in E Africa. Nest excavated by both sexes, at 0.3-20 m in dead tree or dead section of tree, or dead palm, once in telegraph pole; cavity depth 25-30 cm. Clutch 2-4 eggs; no further information.

**Movements.** Mostly resident. Some movement in non-breeding season; recorded in Mauritania at Atar, well N of breeding range, also isolated records from S Nigeria and Ghana coast.

**Status and Conservation.** Not globally threatened. Fairly common to common, and widespread. Commonest woodpecker in Senegambia; common in Sierra Leone. Uncommon in Liberia, estimated population 2000 pairs. Uncommon in Angola; fairly common in Kenya. Occurs in several protected areas, including W National Park (Niger), Bénoué National Park (Cameroon) and Serengeti National Park (Tanzania).

**Bibliography.** Bannerman (1953), Barlow *et al.* (1997), Britton (1980), Brown & Britton (1980), Carroll (1988), Cave & Macdonald (1955), Cheesman & Slater (1935), Cheke & Walsh (1996), Dean (2000), Dowsett (1989b), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Gaugris *et al.* (1981), Gee (1984), Giraudoux *et al.* (1988), Gore (1990), Green (1996), Grimes (1987), Jensen & Kirkeby (1980), Lamarche (1988), Lewis & Pomroy (1989), Lippens & Wille (1976), Louette (1981b), Louette & Prigogine (1982), Mackworth-Præd & Grant (1957, 1962, 1970), Moore (1980), Morel & Morel (1990), Newby (1987), Nikolaus (1987, 2000), Pinto (1983), Prigogine & Louette (1983), Rodwell *et al.* (1996), Sauvage & Rodwell (1998), Schmid (1982), Short (1980, 1985b), Short & Horne (1988b), Short *et al.* (1990), Snow (1978), Tarboton (1997), Urban & Brown (1971), Vande weghe (1981), Wilkinson & Beecroft (1988), Zimmerman *et al.* (1996).

## 86. Grey-headed Woodpecker

### *Dendropicos spodocephalus*

**French:** Pic spodocephale

**German:** Graukopfspecht

**Spanish:** Pito Gris Oriental

**Other common names:** Eastern Grey Woodpecker

**Taxonomy.** *Dendrobates spodocephalus* Bonaparte, 1850, West Africa; error = Shewa, southern Ethiopia.

Often placed with *D. goertae* and *D. griseocephalus* in a separate genus *Mesopicus*, sometimes also including *D. elliotii*; forms a superspecies with the first two, hybridizing with them where ranges meet; often treated as conspecific with *D. goertae*. Two subspecies recognized.

#### Subspecies and Distribution.

*D. s. spodocephalus* (Bonaparte, 1850) - E Sudan and W & C Ethiopian Highlands.

*D. s. rhodogaster* (Fischer & Reichenow, 1884) - highlands of C & SW Kenya and NC Tanzania.

**Descriptive notes.** 20 cm; 43-52 g. Male has red hindcrown and nape, sometimes some grey feather bases visible when worn; entire rest of head grey, including forehead, forecrown and hindneck, ear-coverts sometimes slightly darker; upperparts green, rump and uppertail-coverts red; dark brown flight-feathers edged yellowish-green on outer webs, broadly on tertials, whitish bars on inner webs of primaries and secondaries; uppertail dark brown, outer feathers barred white on outer webs; grey below, red patch from central belly to vent, sometimes to undertail-coverts; underwing barred blackish and white; undertail brown,

outer feathers barred yellowish; fairly long bill straight, broad, slaty-grey to black, paler lower mandible; iris red to brown; legs light greenish-grey, joints white. Differs from *D. goertae* in brighter upperparts, more uniform grey head and underparts, larger and red belly patch, less barred tail; from *D. griseocephalus* mainly in paler general coloration. Female has slightly shorter bill than male, no red on head. Juvenile duller, with red of rump paler, indication of barring below, smaller red belly patch, grey-brown eyes, both sexes with red in crown centre, more extensive on male. Race *rhodogaster* resembles nominate, but has bright yellow feather tips on upperparts, darker under-

parts. **VOICE.** Series of "wik" notes, also irregular series of "weeka" in interactions, very like *D. goertae*. Drums rarely.

**Habitat.** Moist forest, forest edge, and riverine forest, in highlands, up to at least 3300 m.

**Food and Feeding.** Diet includes Geophilidae centipedes, lepidopteran pupae and larvae. Found singly or in pairs at middle levels and on ground. Pecks at trees; hawks insects opportunistically.

**Breeding.** Season Aug-Apr in Ethiopia; breeds in most months in Kenya and N Tanzania, peak in Apr-May and Jul-Oct. Nest-hole in tree; no other details, presumably as for *D. goertae*.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally quite common within its limited range. Quite common in Kenya. Present in several protected areas, e.g. Mt Kenya, Lake Nakuru and Amboseli National Parks (Kenya) and Ngurdoto Crater National Park (Tanzania).

**Bibliography.** Britton (1980), Cheesman & Selater (1935), Friedmann (1930a), Fry *et al.* (1988), Mackworth-Praed & Grant (1957), Prigogine & Louette (1983), Short & Horne (1988b), Short *et al.* (1990), Urban & Brown (1971), Wheatley (1995).

## 87. Olive Woodpecker

### *Dendropicos griseocephalus*

**French:** Pic olive

**German:** Goldrückenpecht

**Spanish:** Pito Oliváceo

**Taxonomy.** *Picus griseocephalus* Boddaert, 1783, Cape of Good Hope.

Often placed with *D. goertae* and *D. spodocephalus* in a separate genus *Mesopicos*, sometimes also including *D. elliotii*; forms a superspecies with the first two, interbreeding where ranges meet. Proposed race *persimilis* (Angola to N Malawi) inseparable from *ruwenzori*. Three subspecies currently recognized.

**Subspecies and Distribution.**

*D. g. ruwenzori* (Sharpe, 1902) - Angolan highlands, and E Zaire and SW Uganda (Ruwenzoris and Impenetrable Forest), S to NC & NE Namibia, SC Zambia and N Malawi.

*D. g. kilimensis* (Neumann, 1926) - Tanzanian highlands: Mt Kilimanjaro, Mt Meru, and mountains of N Pare, Usambara, Uluguru and Udzungwa.

*D. g. griseocephalus* (Boddaert, 1783) - extreme S Mozambique (Lebombo Mts) and E & S South Africa (E Natal to S Cape Province).

**Descriptive notes.** 20 cm; 33-51 g. Male has red hindcrown and nape feathers often with some fine black subterminal bars, grey bases often evident in worn plumage; rest of head, including forehead, forecrown, hindneck, chin and throat, darkish grey; dull olive-green upperparts tinged bronze (brighter in N & E of range); red rump and uppertail-coverts, latter sometimes showing dark bases; wing-coverts edged paler bronze-green; dark brown flight-feathers sometimes with pale spots on inner webs, with olive-green edges sometimes reddish-tinged; uppertail blackish-brown or black, feathers edged olive; bronze-olive below, breast with distinct golden tinge, belly and undertail-coverts much greyer, sometimes very small red patch on belly, occasionally obscure whitish bars on flanks; underwing pale brownish; undertail brownish, yellow tinge to outer feathers; longish bill straight, broad, grey to blackish, lower mandible paler and tinged green or blue; iris brown; legs grey to greyish-olive or olive-grey. Distinguished from *D. goertae* and *D. spodocephalus* by much darker general coloration, unbarred tail, golden breast. Female has shorter bill than male, entirely grey head without red. Juvenile duller, greener above, greyer below, paler red on rump, usually barred below, red belly patch paler if present, both sexes with black-barred red in crown centre, red more extensive on male. Race *ruwenzori* is brighter than nominate, has yellower or more golden tinge above, golden or yellow-olive breast, flight-feathers more clearly barred, red belly patch sometimes fairly extensive; *kilimensis* averages smaller than other races, has less yellow in upperparts, greyer underparts, always lacks red on belly, can have red eyes. **VOICE.** Long, slightly nasal trilled whistle

of 3-4 notes, "whee-whee-whee"; "pep" to "pep-pep-pep" conversational notes within groups; soft "tick" alarm, sometimes followed by contracted trill, "chi-r-r-r-re"; "tweet" on take-off, "wat-chew" in flight; repeated "wer chick" with head movements; also quiet "kiwi-kiwi-kiwi" between two birds at close distance; soft, high-pitched "kee-kee-kee-kee" twitter by nestlings. Drums in soft, fast rolls.

**Habitat.** Forest, evergreen thickets and dense woodland, and forest fringing watercourses, in uplands; usually in more open parts, as in *Hagenia* forest. Shows some preference for forest patches rather than continuous closed

forest. More common inland in evergreen forest; less in thick coastal bush, but the only picid species likely to be found in that habitat type in South Africa. Occurs at altitudes of between 450 m and 3700 m; usually higher up and in denser forest than *D. spodocephalus* on Mt Kilimanjaro (Tanzania); low-level records may involve stragglers.

**Food and Feeding.** Insects and their larvae, particularly ants, beetles (Scarabaeidae). Occurs singly or in pairs, often in parties of up to 6; frequently joins mixed-species feeding flocks. Strictly arboreal, forages on upper trunks and on branches, preferring small trees and small branches in larger trees. Moves quickly through a tree, often shifting sideways or backwards. Forages at 1-24 m; preferred heights between 10 m and 15 m, modal height 12 m. Pecks, often with lateral blows, excavating for large larvae; probes frequently among mosses, gleans from bark.

**Breeding.** Possibly Apr-Jun in Tanzania; breeds Feb-Sept in Zaire, Jul-Sept in Malawi, May-Jul in Zambia, Sept in Natal and Zululand, and Oct-Nov in the Cape; Jun in Angola; sometimes 2 broods in a season. Male helpers present at some nests. Head-swinging displays with calling. Nest-hole excavated mostly by male, at 1-5-18 m in dead trunk or dead branch, sometimes on underside of horizontal branch; territory small. Clutch usually 2 or 3 eggs; both sexes incubate, period 15-17 days; both also feed chicks and tend to nest sanitation, possibly with one or two helpers, female may feed brood more frequently but often with smaller amounts, and collects food close to nest, whereas male makes longer foraging trips; partners roost together in nest during egg and nestling stages; fledging period c. 26 days; often only one young reared successfully, cared for by parents for further 3 months or more, during which family roosts together in nest, or male alone accompanies young; if two juveniles reared, parents accompany one each. Nests parasitized by Scaly-throated Honeyguide (*Indicator variegatus*).

**Movements.** Resident; possibly some local short-distance or vertical movements.

**Status and Conservation.** Not globally threatened. Variably common to uncommon in most of range, but local to scarce in Tanzania; uncommon in Angola; generally common in South Africa. Densities vary from 2-2 pairs/10 ha in forest patches to 0.2-0.3 pairs/10 ha in more continuous forest. Present in several protected areas, e.g. Impenetrable Forest National Park (Uganda), Kahuzi-Biega National Park (Zaire), Nyungwe Forest Reserve (Rwanda), Kibira National Park (Burundi) and Oribi Gorge Nature Reserve and Langeberg, Hlabeni, Balgoan and Ngoye Forest Reserves (South Africa).

**Bibliography.** Benson & Benson (1977), Benson *et al.* (1971), Britton (1980), Brown & Britton (1980), Clancey (1992), Dean (2000), Dowsett (1990), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire (1983c), Earlé (1989), Fry *et al.* (1988), Ginn *et al.* (1989), Harrison *et al.* (1997), Holland (1997), Irwin (1981), Leonard (1998a), Lippens & Wille (1976), Liversidge (1959), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), Pinto (1983), Richardson (1989), Short (1980, 1985b), Short & Horne (1988b), Short *et al.* (1990), Sigfried (1989), Snow (1978), Tarboton (1997, 2001), Tarboton *et al.* (1987), Van der Merwe (1986), Vande weghe (1981), Zimmerman *et al.* (1996).

Genus *DENDROCOPOS* Koch, 1816

## 88. Brown-backed Woodpecker

*Dendrocopos obsoleteus*

French: Pic à dos brun

German: Braunrückenspecht

Spanish: Pico Dorsipardo

Other common names: Lesser White-spotted Woodpecker

**Taxonomy.** *Picus obsoleteus* Wagler, 1829, Senegambia.

Genus sometimes merged into *Picoides*. Species has also been included with other African species in *Dendropicops*, but probably more closely related to Asian *D. temminckii*, *D. maculatus* and *D. moluccensis*. S Ethiopian birds described as a separate race *nigricans*, but considered indistinguishable from *ingens*. Four subspecies recognized.

**Subspecies and Distribution.**

*D. o. obsoleteus* (Wagler, 1829) - Senegambia E to W Sudan and Uganda (E to Teso), S to C Sierra Leone, S Cameroon and NE Zaire.

*D. o. heuglini* (Neumann, 1904) - E Sudan, N Ethiopia and Eritrea.

*D. o. ingens* (Hartert, 1900) - WC & S Ethiopia, NE Uganda, W & C Kenya and extreme N Tanzania (Loliondo).

*D. o. crateri* (W. L. Sclater & Moreau, 1935) - N Tanzania from Crater Highlands S to Nou Forest.

**Descriptive notes.** c. 13-16 cm; 18-25 g. Male has pale brown forehead becoming darker on crown, red hindcrown and nape; white supercilium from behind eye, extending as stripe behind ear-coverts and down neck side to breast; brown ear-coverts, white cheekstripe, dark brown malar stripe expanding on upper breast side; white chin and throat sometimes with small dark spots; dull brown hindneck and upperparts, white rump and uppertail-coverts streaked brown; wing-coverts tipped white (amount of spotting variable); dark brown flight-feathers barred white; uppertail brown, barred white; whitish below, breast often

washed buff-brown and lightly streaked brown (streaks occasionally almost absent); longish bill straight, chisel-tipped, blackish, paler lower mandible; iris red-brown; legs grey, often tinged green. Female has on average shorter bill than male, hindcrown and nape brown, not red. Juvenile somewhat darker above than adult, plumage tinged greyish, eyes brown, usually some barring below, both sexes with red on hindcrown, more extensive on male. Race *heuglini* is larger than nominate, has much-reduced or no spotting on wing-coverts, heavier streaking below; *ingens* resembles previous, but darker above, especially on crown, has spotted wing-coverts; *crateri* is larger and darker than others, has upperparts almost black, very broad and dark streaks below meeting to form patch on breast. VOICE. Single clicking call; weak high-pitched trill; also longer or shorter series of "kweek-week". Drums.

**Habitat.** Inhabits drier areas, favouring scrubby terrain, wooded grassland, edges of cultivation, *Combretum* woodland and *Hagenia* forest; commonly occupies *Lophira* woodland in Sierra Leone; also open savanna with scattered trees. Occurs quite regularly in suburban gardens. Found in highlands to 2300 m, locally to 3000 m (Mt Kenya), but also down to sea-level; more in lowlands in W Africa.

**Food and Feeding.** Lepidopteran and coleopteran larvae, and various adult insects; also fruits recorded. Usually singly or in pairs; often joins mixed-species flocks. Forages on thin trunks and branches of trees, frequently on saplings; uses gleaning and pecking.

**Breeding.** Dec-Jun in W of range, Jan-Apr and Aug in E. Nest-hole excavated by both sexes, at 2-7 m in tree or stub, often isolated one. Clutch 2 eggs; both parents incubate and both feed chicks; incubation and fledging periods not recorded.

**Movements.** Apparently resident. Individuals recorded in SE Kenya (E to Shimba Hills and Mom-basa area) and NE Tanzania (near Arusha) presumably wanderers.

**Status and Conservation.** Not globally threatened. Rather local and generally uncommon. Widespread in Senegal; locally frequent to common in Gambia; not uncommon in Sierra Leone; local and uncommon in Kenya and Tanzania. Occurs in a number of protected areas throughout its range, including Niokola Koba National Park (Senegal), Comoé National Park (Ivory Coast), Bénoué National Park (Cameroon) and several parks and reserves in E Africa. Probably reasonably secure; no known threats.

**Bibliography.** Bannerman (1953), Barlow *et al.* (1997), Brown & Britton (1980), Carroll (1988), Cave & Macdonald (1955), Cheesman & Sclater (1935), Cheke & Walsh (1996), Demey *et al.* (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fry *et al.* (1988), Giraudoux *et al.* (1988), Gore (1990), Green (1990), Greig-Smith (1977b), Grimes (1987), Jensen & Kirkeby (1980), King (2000), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981b), Mackworth-Præd & Grant (1957, 1970), Morel & Morel (1990), Nikolaus (2000), Ouellet (1977a), Rodwell (1996), Salewski (2000), Sauvage & Rodwell (1998), Short (1971d, 1980, 1985b), Short *et al.* (1990), Smith (1957), Snow (1978), Tarboton (1997), Urban & Brown (1971), Wilkinson & Beercoft (1988), Winkler & Short (1978), Zimmerman *et al.* (1996).

## 89. Sulawesi Woodpecker

*Dendrocopos temminckii*

French: Pic de Temminck

German: Temminckspecht

Spanish: Pico de Célebes

Other common names: Celebes/Sulawesi Pygmy Woodpecker, Temminck's (Pygmy) Woodpecker

**Taxonomy.** *Picus Temminckii* Malherbe, 1849, Sulawesi.

Genus sometimes merged into *Picoides*. Forms a superspecies with *D. maculatus*. Populations in S and uplands tend to be somewhat larger than those in N and lowlands, but no grounds for racial subdivision. Monotypic.

**Distribution.** Sulawesi, including Togian Is and Buton.

**Descriptive notes.** 13-14 cm. Male has buff-brown lower forehead, dark brown upper forehead and crown with grey feather bases, in worn plumage appearing streaked; narrow red napeband (red often lacking on central nape); narrow white supercilium from front edge of eye to nape side, dark brown ear-coverts (grey-streaked when worn); broad white cheekband expanding on neck side, often extending to central hindneck; brown malar stripe thinly barred white; dull, pale greyish-brown chin and throat, sometimes extensively marked with off-white; olive-brown upperparts sometimes tinged green, barred very pale brownish-white;

whitish rump barred dark brown, occasionally pale yellowish-white or unbarred; uppertail-coverts barred brown and white; dark brown wing-coverts and tertials with faint olive tinge, coverts tipped white, tertials barred white; darker brown primaries and secondaries barred white on both webs; uppertail brown, buffish or buff-white bars of variable width; pale buffish-olive to yellowish-grey below, broadly streaked brown or olive-brown, lower underparts paler and more narrowly streaked; undertail paler than above, usually with slight yellowish wash; longish bill pointed, culmen slightly curved, black, greyer base of lower mandible; iris red to light brown; legs olive-green. Female has no red on nape. Juvenile browner, with barring above and streaking below less prominent. VOICE. Sharp "tirr-tirr"; also rapid, thin "geegeegeegeegeegee". Drums.

**Habitat.** Wooded areas, including secondary forest, riparian woodland, orange and coffee plantations in cultivated lowlands, large trees along roadsides, and gardens; also in deforested hills and at edges of primary montane forest, at up to 2300 m.

**Food and Feeding.** Details of diet not known; thought to be similar to that of *D. maculatus*. Spends most of its time high up in treetops.

**Breeding.** Drumming and copulations recorded in Aug; probably breeds also early in year. Nest-hole in dead tree, preferentially rain-tree (*Pithecolobium*) but also e.g. mango (*Mangifera indica*), or in dead branch. No other information.

**Movements.** Resident and sedentary.

**Status and Conservation.** Not globally threatened. Not uncommon within its range. Occurs in Lore Lindu, Dumoga-Bone and Rawa Aopa National Parks, and Manembonbo and Tangkoko Nature Reserves; common in Gunung Ambang Nature Reserve in NE Sulawesi. Seems to be fairly adaptable.

**Bibliography.** Andrew (1992), Bororing *et al.* (2000), Catterall (1997), Coates & Bishop (1997), Ekstrom *et al.* (1998), Fraser & Henson (1996), Holmes & Philipps (1996), Inskipp *et al.* (1996), Ouellet (1977a), Riley & Mole (2001), Rozendaal (1989), Wardill (1995), Watling (1983), Wheatley (1996), White (1977), White & Bruce (1986), Winkler & Short (1978).

## 90. Philippine Woodpecker

*Dendrocopos maculatus*

French: Pic des Philippines

German: Scopolispecht

Spanish: Pico Filipino

Other common names: Pygmy Woodpecker(!), Philippine Pygmy Woodpecker, Sulu Woodpecker (*ramsayi*)**Taxonomy.** *Picus maculatus* Scopoli, 1786, Antigua, Panay, Philippines.

Genus sometimes merged into *Picoides*. Forms a superspecies with *D. temminckii*. Distinctive race *ramsayi* may be a separate species, perhaps even derived from *D. temminckii*, on basis of plumage and vocal differences; further study needed. Other named races are *menagei* (Sibuyan), *leytensis* (Samar, Calicoan, Leyte, Bohol), *apo* (Mt Apo, on Mindanao) and *siasiensis* (Siasi I, in Sulus), all considered insufficiently distinct. Four subspecies recognized.

**Subspecies and Distribution.**

*D. m. validirostris* (Blyth, 1849) - Luzon, Lubang, Marinduque, Mindoro and Catanduanes.

*D. m. maculatus* (Scopoli, 1786) - Sibuyan, Panay, Gigantes, Guimaras, Negros and Cebu.

*D. m. fulvifasciatus* (Hargitt, 1881) - Samar, Calicoan, Leyte, Bohol, Dinagat, Mindanao and Basilan.

*D. m. ramsayi* (Hargitt, 1881) - Sulu Is.

**Descriptive notes.** 13-14 cm; 22-30 g. Male has dark brown forehead to hindcrown, blacker at sides, small red patch at side of hindcrown (sometimes extending across rear nape); white supercilium from rear of eye to nape side, blackish-brown ear-coverts back to hindneck; buffish-brown upper lores, white lower lores and broad band through cheek to lower neck side; dark brown malar stripe variably spotted or streaked white; white chin, greyer throat and uppermost breast, brown spotting on lower throat and throat sides; dark brown hindneck and upperparts, white bars on lower mantle, scapulars and back, whiter rump with a few

dark spots or bars; white uppertail-coverts broadly streaked dark; brown upperwing darker on primaries and secondaries, coverts narrowly tipped white, flight-feathers narrowly barred white; uppertail dark brown, barred white; underparts below throat pale buffish-white, breast washed yellow-buff and with dark brown spots, belly and flanks streaked, whitish undertail-coverts broadly streaked dark; fairly long bill slightly chisel-tipped, culmen barely curved, dark grey, paler base; iris brown to brownish-red; legs brownish to olive-brown. Female has slightly longer bill, wing and tail than male, lacks red on hindcrown. Juvenile much as adult, but browner with heavier pale barring above, markings below less sharp. Race *validirostris* is shorter-tailed than nominate, darker above, has rump more barred (often fully so), white supercilium usually continuing behind ear-coverts, male with red reduced to small line on hindcrown side; *fulvifasciatus* is still darker than previous, almost black above, has pale bars tinged buff, rump unmarked white, more white behind ear-coverts (often meeting white of supercilium), stronger buff wash below; *ramsayi* highly distinctive, browner and unbarred above, broad, irregular white streaks on back, rump mostly white, pale wing markings reduced to small bars on inner webs of flight-feathers, hardly streaked below and few or no spots,

instead a brownish breastband with yellow or golden lower border, male with red over entire nape and along rear crown side. VOICE. Slightly descending stuttered series, "pilt-pilt-pilt-pilt", c. 2-2.5 seconds long, irregularly repeated; *ramsaii* apparently a slightly lower "kikikikikiki", rising at start; also single "pilt", more commonly "piti"; single "chrit" notes apparently as long-distance signals. Drums.

**Habitat.** Light to dense primary and secondary forest to cloudforest, mature mixed plantations, forest edge, and woods along rivers, also grassy clearings with scattered trees; typically, in areas with many dead, often rather small, trees. Forages out into recently burned clearings where dead trees present. Also mangroves in Sulu Is (*ramsaii*). From sea-level, but mostly above 500 m, to 1350 m, locally to 2500 m.

**Food and Feeding.** Insects, mostly ants, also grubs and other larvae. Singly, in pairs, or in small family parties of up to 5 birds; often joins mixed-species flocks with tits (Paridae), nuthatches (*Sitta*) and other small birds. Forages mostly in upper levels, above 9 m, on twigs and smaller branches, also on trunks; dead trees or trees with dead branches clearly favoured. Pecks and hammers, and gleans from bark and foliage.

**Breeding.** Season Feb-Aug; nestlings found in Feb. Nest-hole in tree; no other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Race *ramsaii* Vulnerable. Generally common, and the most abundant woodpecker within its range; appears reasonably adaptable, but little is known of its breeding biology and requirements. Further study needed. Sulu race *ramsaii*, currently listed as Vulnerable but perhaps better classified as Endangered, is known to survive for certain only on Tawitawi, and at only three sites there, with greatly restricted range of at most 1760 km<sup>2</sup> and decreasing; despite apparent tolerance of degraded habitats, its numbers have continued to decline rapidly; was widespread and abundant on eight islands in Sulu Archipelago in first half of 20th century, since when extensive or complete destruction of habitat on most islands has resulted in its total disappearance from all but one; even the few remaining forest patches on Tawitawi are highly degraded, and further threatened by uncontrolled logging and plans for conversion to commercial plantations of oil palms (*Elaeis guineensis*). Despite initiatives to raise awareness of importance of conservation in the region, and especially on Tawitawi, no formally protected areas exist anywhere in Sulu chain; campaigns and surveys urgently needed, but political problems make all conservation efforts difficult and dangerous. It seems likely that *ramsaii* will end up being generally treated as a distinct species, and this could, theoretically, be of help in gaining protection of the handful of sites known to harbour this woodpecker.

**Bibliography.** Alcalá & Sanguila (1969), Brooks, Dutton *et al.* (1996), Brooks, Evans *et al.* (1992), Collar *et al.* (1999), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), Dutton, Allen & Brooks (1996), Dutton, Evans *et al.* (1992), Evans *et al.* (1993), Gilliard (1950), Goodman & Gonzales (1990), Hachisuka (1931-1935), Inskipp *et al.* (1996), Lambert (1993), McGregor (1904, 1905, 1909-1910), Mearns (1909), Ouellet (1977a), Pardo & Gogorza y González (1997), Parkes (1958, 1971), duPont (1971), duPont & Rabor (1973), Potter (1953), Rabor (1977), Rand & Rabor (1960), Salomonsen (1953), Stattersfield & Capper (2000), Winkler & Short (1978).

## 91. Brown-capped Woodpecker

### *Dendrocopos moluccensis*

**French:** Pic nain **German:** Braunscheitelspecht **Spanish:** Pico Crestipardo  
**Other common names:** Brown-capped Pygmy Woodpecker; Sunda/Malaysian Woodpecker/Pygmy Woodpecker (nominate group); Indian Pygmy Woodpecker (*nanus* group); Ceylon/Sri Lanka Pygmy Woodpecker (*gymnophthalmos*)

**Taxonomy.** *Picus moluccensis* J. F. Gmelin, 1788, Moluccas; error = Malacca.

Genus sometimes merged into *Picoides*. Closest to *D. temminckii* and *D. maculatus*. Indian Subcontinent races often treated as forming a separate species on grounds of shared morphological differences from E races. Alternatively, race *nanus* has sometimes been considered conspecific with *D. canicapillus*, but the two are sympatric in Nepal without interbreeding. Birds in E peninsular India described as race *hardwickii*, and those from Alor (E Lesser Sundas) as *excelstor*, but in both cases differences are a result of clinal variation. Five subspecies recognized.

#### Subspecies and Distribution.

- D. m. nanus* (Vigors, 1832) - N and peninsular India (except SW) and S Nepal E to Bangladesh.
- D. m. cinereigula* (Malherbe, 1849) - SW India in Kerala and W Tamil Nadu.
- D. m. gymnophthalmos* (Blyth, 1849) - Sri Lanka.
- D. m. moluccensis* (J. F. Gmelin, 1788) - W & S Peninsular Malaysia S to Greater Sundas, including Riau Archipelago, Bangka and Belitung.
- D. m. grandis* (Hargitt, 1882) - Lesser Sundas, from Lombok E to Alor.

**Descriptive notes.** 13 cm; 13-17 g (*nanus* group), 15-18 g (*moluccensis* group). Male has blackish-brown forehead to hindneck, small red line at side of hindcrown, broad blackish-brown band through ear-coverts and down neck side, prominent dark malar stripe continuing to breast side; rest of head white; blackish-brown upperparts barred white, white rump and uppertail-coverts spotted and barred blackish, wing-coverts with white spots at tips, flight-feathers with white spots forming bars; uppertail blackish-brown, central feathers with white spots, outer bars white; whitish underparts browner on breast, heavily dark-streaked; underwing and undertail barred brown and white; shortish bill rather straight, slightly chisel-tipped, grey, pale inner half; iris light brown; legs greyish. Differs from *D. canicapillus* mainly in smaller size, darker forehead, more solid facial markings, broader streaks below. Female lacks red on hindcrown. Juvenile like adult but browner, duller, less contrastingly patterned, male with orange to red on nape more extensive than on adult. Race *grandis* is bigger and longer-tailed than nominate, has malar usually white-streaked, rump generally less barred, pale wingbars broader, underparts often washed yellow-buff and more finely streaked, tends to become larger and less heavily streaked from W to E; *nanus* is browner, crown sometimes tinged yellowish, lacks dark malar, has white eyes, bare red orbital ring, more elongated wing-covert spots, whitish underparts washed very pale buff with little or no streaking; *cinereigula* is darker than previous, especially on crown, has less white in wing, streaks below very fine (can appear unstreaked); *gymnophthalmos* is small, even darker, more sooty-black, above, with blackish crown, underparts unstreaked. VOICE. Common call a fast trilled "kikikikikiki" or "rrrrrr-i-i" or "click-rrr". Drums, c. 7 rolls per minute.

**Habitat.** Light deciduous forest, secondary forest, bamboo, trees near cultivation, also tall trees near villages, old plantations, sometimes parks and gardens; also coastal scrub and mangroves, and

*Casuarina* trees, especially in E of range. Mainly semi-evergreen forest and lower montane forest in Lesser Sundas. Mostly in lowlands, up to 1200 m in SW India and Sri Lanka; to 2200 m in Lesser Sundas.

**Food and Feeding.** Insects, particularly ants and other hymenopterans, beetles and their larvae, caterpillars; fruits, berries and flower nectar also taken. Usually solitary, also in pairs and family parties; joins mixed-species flocks. Moves slowly over dead trees or dead parts of trees when foraging for ants and other insects; prefers smaller branches and twigs high up in trees, also forages on thin stems of shrubs close to ground. Gleaning from surface seems to be the commonest feeding method; also probes under surface layers of bark; sometimes hammers feverishly and loudly, but in most cases delivers only few pecks.

**Breeding.** Jan-Jul, mainly Mar-Apr, in Indian Subcontinent, in Sri Lanka also Oct-Dec when conditions favourable; Mar-Aug in Peninsular Malaysia, and Apr-Jul, also Oct, in Sundas. Nest-hole excavated at 2-14 m, mostly 4-10 m, in small dead branch, often on underside; entrance diameter c. 3-3 cm. Clutch 2-3 eggs, occasionally 4; details of incubation and fledging periods not known.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Locally fairly common in Indian Subcontinent; status in Bangladesh uncertain, probably rare resident. Uncommon to locally common in Peninsular Malaysia and Greater and Lesser Sundas. Occurs in numerous protected areas, e.g. Keoladeo Ghana and Ranthambore National Parks (India), Sigiriya Sanctuary and Kelani River and Bodhinagala Forest Reserves (Sri Lanka), Bako National Park (Malaysia), Sungei Buloh Nature Park (Singapore), Way Kambas National Park (Sumatra), Baluran National Park (Java) and Bali Barat National Park (Bali). Increases in numbers in some areas where forests are opened up; appears to be fairly adaptable.

**Bibliography.** Ali (1996), Ali & Ripley (1983), Andrew (1992), van Balen & Prentice (1978), Betts (1934), Chasen (1937), Chasen & Hoogerwerf (1941), Coates & Bishop (1997), Davison (1997), Duckworth & Kelsh (1986), Grimmett *et al.* (1998), Hails & Jarvis (1987), Harrison (1999), Harvey (1990), Henry (1998), Hoffmann (1999), Holmes (1996, 1997), Holmes & van Balen (1996), Holmes & Burton (1987), Inskipp, C. ## 92. Grey-capped Woodpecker

### *Dendrocopos canicapillus*

**French:** Pic à coiffe grise **German:** Grauscheitelspecht **Spanish:** Pico Crestigrís  
**Other common names:** Grey-headed Woodpecker(!), Pygmy Woodpecker(!), Grey-crowned Woodpecker(!); Taiwan/Formosan Woodpecker ("watersi")

**Taxonomy.** *Picus canicapillus* Blyth, 1845, Ramree Island, Arakan, Myanmar.

Genus sometimes merged into *Picoides*. Most closely related to *D. kizuki* and sometimes thought to form a superspecies with it, although ranges of the two overlap rather extensively in mainland E Asia; more distantly related to *D. temminckii*, *D. maculatus* and *D. moluccensis*. Has at times been considered conspecific with race *nanus* of *D. moluccensis*, in which case name *nanus* has priority; however, the two are sympatric in Nepal without interbreeding. Mainland races intergrade. Taiwan population originally named as a separate species, "*D. watersi*", but specimen shown to be juvenile of present species; name subsequently synonymized with *kaleensis*. Other named races include *szetshuanensis* (C China), *nagamichi* (E China), *omissus* (SW China), *obscurus* (SE Yunnan) and *tonkinensis* (Tonkin), all considered either to represent intergrades between populations or to fall within range of variation of adjacent races. Eleven subspecies recognized.

#### Subspecies and Distribution.

- D. c. mitchellii* (Malherbe, 1849) - N Pakistan E to Nepal.
- D. c. semicoronatus* (Malherbe, 1849) - extreme E Nepal E to W Assam.
- D. c. canicapillus* (Blyth, 1845) - E Assam, Bangladesh, C & S Myanmar, most of Thailand and Laos.
- D. c. delacouri* (Meyer de Schauensee, 1938) - SE Thailand, Cambodia and CochinChina.
- D. c. auritus* (Eytton, 1845) - S Thailand and Peninsular Malaysia.
- D. c. volzi* (Stresemann, 1920) - Riau Archipelago and Sumatra, including Nias I.
- D. c. auraniventris* (Salvadori, 1868) - Borneo.
- D. c. doerriesi* (Hargitt, 1881) - E Siberia (Ussuriland), E Manchuria and Korea.
- D. c. scintilleps* (Swinhoe, 1863) - E & C China from Liaoning S to Sichuan and Zhejiang.
- D. c. kaleensis* (Swinhoe, 1863) - W & S Sichuan E to Fujian and Taiwan, and S to N Myanmar and N Indochina.
- D. c. swinhoei* (Hartert, 1910) - Hainan.

**Descriptive notes.** 14-16 cm; 20-27 g (*mitchellii*), 21-32 g (*semicoronatus*, *scintilleps*). Male has grey forehead and crown, black crown sides, hindcrown and nape, small red streak on nape side, buffish nasal tufts; white face with grey-brown band through lower ear-coverts, darker at rear and continuing down neck side, narrow brownish malar stripe; whitish chin and throat; black upperparts tinged brown, barred white, wing-coverts with variable amount of white at tips; black flight-feathers tipped white, white spots forming bars on inner wing; uppertail black, central feathers barred or spotted white, outer 2 or 3 pairs barred whitish; whitish below.

breast strongly tinged brownish, dark brown streaks most pronounced on breast; fairly long bill almost straight, barely chisel-tipped, blackish, paler base and lower mandible; iris red-brown to grey-brown, orbital skin grey; legs greyish to olive-grey. Female lacks red on crown. Juvenile is darker above than adult, with crown blackish, darker below with heavier streaking and often hint of barring, male with orange-red on nape and rear crown sides often more extensive than on adult. Races vary in both plumage and size: *semicoronatus* has buffish cheekband, strong yellow-brown to buff or even orange-tinge below, differs from all others races in that male has red extending across nape; *mitchellii* is very like previous, but red on male restricted to narrow lateral nape streak, often more extensive brown on face; *delacouri* resembles nominate, but larger, with broader dark streaking below; *auritus* has head pattern clearly defined, is slightly shorter-tailed, with plumage blacker, less brown-toned, grey-brown breastband, central rectrices barred on some, plain on others; *volzi* has less white in wings, orangey to orange-gold underparts; *aurantiventris* is smallest race, resembles previous but has longer bill, shorter tail, often more pronounced malar; *doerriesi* is largest race, distinctive, has mantle and upper back black, lower back and rump white, uppertail-coverts black, wing-coverts with much white forming

patches, wingbars broad, pale underparts with streaks rather narrow; *scintilliceps* is similar to previous but slightly smaller, with upper back barred white, less white in wings, darker and more heavily streaked below; *kaleensis* is like previous but more streaked below; *swinhoi* is slightly smaller than previous, whiter below with narrower streaking, has more white in wings. VOICE. Short, soft “cheep” or “pic” or “tziit”; doubled “chip-chip”, second note shorter and lower-pitched; also “tit-tit-erh-r-r-r-h”, “pic-chirru-chirru-chihihih” or “click-r-r-r”, and irregular squeaking series, “kweek-kweek-kweek”. Drumming sounds muted.

**Habitat.** Inhabits a great variety of forests and woodlands. Oak (*Quercus*), deciduous and mixed forest in N parts of range. In Nepal and E to SE Asia, occurs in closed as well as more open forest, including sal (*Shorea*) forest, deciduous and open evergreen woodland, second growth, scrub and gardens, but avoids very dense forest; also in *Casuarina* forest and mangroves in coastal SE Asia. Frequents lowland forest, montane forest and pine (*Pinus*) forest, and found also at jungle clearings, in Greater Sundas. Lowlands to 400 m in Nepal, less commonly to 1350 m, and to 1700 m, occasionally 2000 m, elsewhere in Himalayas; to 1830 m in SE Asia; mainly lowlands up to 1680 m in Borneo, and in Sumatra found mostly at 1000-2800 m; to 2000 m in China.

**Food and Feeding.** Diet includes caterpillars, homopterans, small beetles, insect pupae, grubs, Diptera, ants, and fruits; seeds (grass) and other plant matter (e.g. carmine cherries) of some importance in winter. Solitary, in pairs, or in small family groups. Forages in crowns of tall trees, also at edges of bushes and saplings; seeks out dead twigs or stubs, but most foraging is on outer twigs and branches. Frequently perches crosswise, and hangs on twigs and leaf clusters, often upside-down. Does not peck and hammer at one spot for very long; undertakes much gleaning; occasionally removes a piece of bark or lichen and probes into crevices and at base of leaves. Even flutters to catch less accessible items.

**Breeding.** Apr-Jul in Indian Subcontinent and Dec-Apr in SE Asia; somewhat later in N parts of range. Display with crest-raising, bill-directing, and slow body-swinging and tail-spreading. Nest excavated by both sexes, at 2.5-15 m, mostly 5-10 m, in tree branch, particularly on underside. Clutch 3-5 eggs in S of range, 6-8 in N; incubation by both sexes, period 12-13 days; both also feed chicks, nestling period c. 21 days.

**Movements.** Largely resident. Minor post-breeding movements down to lowlands in N parts of range. Probably only a breeding visitor to Pakistan.

**Status and Conservation.** Not globally threatened. Locally common to fairly common in much of range. Rare and very local in Pakistan; in Nepal, rare in W and more common in E; locally fairly common in India and Bhutan; local and not common in Bangladesh, but status uncertain; common throughout most of SE Asia; fairly widespread but uncommon in China, including Hainan; rare and local in NE of range. Occurs in several protected areas, e.g. Corbett National Park (India) and Chitwan National Park (Nepal).

**Bibliography.** Ali & Ripley (1983), Ali *et al.* (1996), Andrew (1992), Baker (1919), Bangs & Van Tyne (1931), Biswas (1950), Bucknill & Chasen (1990), Chasen & Hoogerwerf (1941), Davison (1997), Deignan (1945), Dementiev *et al.* (1966), Duckworth & Kelsh (1988), Eames & Robson (1992), Échécopar & Hue (1978), Friedmann (1997), Greenway (1943), Grimmett *et al.* (1998), Harvey (1990), Holmes (1996, 1997), Holmes & Burton (1987), Inskipp, C. (1989), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Jeyarajasingam & Pearson (1999), King & Rappole (2001), Knystautas (1993), Lekagul & Round (1991), Ludlow (1937), MacKinnon (1988), MacKinnon & Phillips (1993, 2000), Madoc (1976), van Marle & Voous (1988), Medway & Wells (1976), Meyer de Schauensee & Ripley (1940), Ouellet (1977a), Riley (1938), Ripley (1982), Roberts (1991), Robson (2000), Sargeant (1997), Severinghaus & Blackshaw (1976), Short (1973d), Smythies (1986, 1999), Stepanyan (1995), Thompson *et al.* (1993), Tsai Hanyeh (1985), Verheugt *et al.* (1993), Vowles & Vowles (1997), Wells (1985, 1999), Winkler & Short (1978), Won Pyongoh (1993), Zhao Zhengjie (1995), Zhou Shie *et al.* (1980).

93. Pygmy Woodpecker

*Dendrocopos kizuki*

**French:** Pic kisuki                      **German:** Kizukispecht                      **Spanish:** Pico Kizuki  
**Other common names:** Japanese Pygmy/Spotted Woodpecker, Japanese Woodpecker(!)

**Taxonomy.** *Picus kizuki* Temminck, 1835, Kyushu. Genus sometimes merged into *Picoides*. Has been thought to form a superspecies with *D. canicapillus*, although their ranges overlap rather extensively in NE Asia. Varies clinally, becoming smaller and darker from N to S. Described mainland races *permutatus* (Sidemi, in Ussuriland), *wilderi* (NE Hebei) and *acutirostris* (E Korea), and island races *kurilensis* (Kuril Is), *nippon* (Honshu), *shikokuensis*

(S Honshu and Shikoku), *matsudairai* (Izu Is), *kotataki* (Oki and Tsushima), *nigrescens* (Okinawa) and *orii* (Iriomote in S Ryukyus), all considered insufficiently distinct. Four subspecies recognized.

**Subspecies and Distribution.**

*D. k. ijimae* (Takatsukasa, 1922) - SE Siberia (S Ussuriland) and Sakhalin S to NE Korea, N Japan (Hokkaido) and S Kuril Is.

*D. k. seebohmi* (Hargitt, 1884) - Korea (except NE), Quelpart I (Cheju-do) and Honshu.

*D. k. kizuki* (Temminck, 1835) - NE China (S to Shandong), and S Japan including Tsushima, Shikoku, Kyushu, Izu Is, and S Ryukyu Is (S to Iriomote).

*D. k. amamii* (Kuroda, 1922) - Amami and Tokunoshima in N Ryukyus.

**Descriptive notes.** 13-15 cm; 18-26 g. Male has grey-brown forehead and crown, darker hindcrown and hindneck, small red patch at nape side (often concealed by overlying feathers) with white patch behind, short white supercilium behind eye, brown ear-coverts and band on neck side continuing to breast side; whitish lores and moustachial stripe, grey-brown malar stripe, white chin and throat; dark brown upperparts darker rearwards and on wing-coverts, all barred white, brownish-black flight-feathers barred white; uppertail blackish, outer feathers white with dark bars near tips; white below, breast and sides washed pale

brown, heavily streaked dark brown, undertail-coverts lightly barred; short bill straight, slightly chisel-tipped, grey-black, paler base; iris brown to red-brown; legs grey. Differs from *D. canicapillus* in smaller size, browner coloration, less white on head. Female has slightly longer wing, bill and tail than male, lacks red on nape side. Juvenile has greyer below than adult, throat streaked and spotted, male with small red patch in crown centre. Race *ijimae* is larger, has white band down neck side, often longer white supercilium, also less streaking below, no bars on vent; *seebohmi* is smaller and darker than previous, has less white above, heavier streaks below; *amamii* is blacker above, has rich buff-brown on flanks, barred undertail-coverts. VOICE. Distinctive, buzzing “kzz, kzz” notes, also soft “khit” or “khit-khit-khit”. Drums weakly, very short rolls in rapid succession.

**Habitat.** Ranges from lowland woods to subalpine mixed coniferous forest, and from subtropical evergreen to N boreal forests with firs (*Abies*) and birches (*Betula*); broadleaved deciduous and mixed forest in riverine lowlands in Ussuri region. Besides deciduous woodland, occupies light stands of pine (*Pinus densiflora*) in Japan and dense montane coniferous forest in Korea. Also in parks and gardens, even in major cities, especially in Japan. Sea-level to 1300 m on mainland, and to c. 2100 m in Japan.

**Food and Feeding.** Mainly arthropods: insects and their pupae, caterpillars, weevils (Curculionidae), aphids, small ants of genera *Lasius* and *Formica*, and spiders. Some berries (*Rhus*) taken; exceptionally, small lizards. Met with singly, in pairs or in family parties; frequently in mixed-species flocks with tits (Paridae) and nuthatches (*Sitta*). Hammers and excavates bark of thin trunks and twigs, also visits stronger herbaceous plants; during breeding season, predominant foraging method is gleaning in the canopy.

**Breeding.** Late Apr to end May in Amur-Ussuri region; in Japan, from late May or early Jun in N and from Mar in S. Monogamous and solitary, but helping by a third adult once recorded. Nest dug into soft, rotten stump at height of 2-10 m, mostly below 7 m; active nests sometimes attacked by conspecifics when available sites in short supply. Clutch 5-7 eggs, exceptionally 9 recorded; incubation period 12-14 days; fledging period c. 3 weeks.

**Movements.** Mostly resident; minor altitudinal movements to lowlands take place in winter in N parts of range.

**Status and Conservation.** Not globally threatened. Fairly common; in Japan the commonest woodpecker. Rarer in S parts of range; generally uncommon in Siberia and China. Adaptable species, able to live in relatively close proximity to humans; colonization of urbanized environments indicates that it is unlikely to become threatened in the near future, although lack of suitable nest-sites in city parks could be a problem. Present in Kirishima-Yaku and Sarak-San National Parks (Japan). **Bibliography.** Austin (1948), Brazil (1991), Dementiev *et al.* (1966), Échécopar & Hue (1978), Friedmann (1997), Ham Kyuhwang (1982), Higuchi (1980), Inskipp *et al.* (1996), Ishida (1994), Kiyosu (1936), Knystautas (1993), MacKinnon & Phillips (2000), Nakamura *et al.* (1995), Sugiyama & Akatsuka (1999), Winkler & Short (1978), Won Pyongoh (1993), Yamagami (1992), Yoon Moohoo (1992), Zhao Zhengjie (1995).

PLATE 33

## 94. Lesser Spotted Woodpecker

*Dendrocopos minor*

French: Pic épeichette

German: Kleinspecht

Spanish: Pico Menor

Other common names: Lesser Pied Woodpecker

**Taxonomy.** *Picus minor* Linnaeus, 1758, Sweden.

Genus sometimes merged into *Picoides*. Related to *D. canicapillus* and *D. kizuki*. Recent genetic data suggest also a link to North American "*Picoides pubescens* group". Races intergrade extensively over species' huge range, with many intermediate populations; numerous additional races have been described, but often on rather weak grounds, and differences are often part of a clinal variation. Named races not accepted include *hispaniae* (Spain), *jordanii* (C European mountains), *serbicus* (Montenegro), *wagneri* (Romania), *hyrcanus* (N Iran), *mongolicus* (SW Siberia to Mongolia), *nojidoensis* (NE Korea) and *immaculatus* (Kamchatka). Eleven subspecies recognized.

**Subspecies and Distribution.***D. m. minor* (Linnaeus, 1758) - N Europe from Scandinavia E to Ural Mts.*D. m. kamtschakensis* (Malherbe, 1861) - Urals E to R Anadyr and Kamchatka.*D. m. amurensis* (Buturlin, 1908) - lower R Amur and Sakhalin S to NE Korea and N Japan (Hokkaido).*D. m. comminutus* Hartert, 1907 - SC & S Britain.*D. m. hortorum* (C. L. Brehm, 1831) - France E to Poland and S to Switzerland, Hungary and N Romania.*D. m. buturlini* (Hartert, 1912) - Iberia, S France and Italy E to Romania, Bulgaria and N Greece.*D. m. ledouci* (Malherbe, 1855) - N Africa (NE Algeria, NW Tunisia).*D. m. danfordi* (Hargitt, 1883) - Greece and Turkey.*D. m. colchicus* (Buturlin, 1908) - Caucasus and Transcaucasia.*D. m. quadrifasciatus* (Radde, 1884) - Lenkoran region of SE Transcaucasia.*D. m. morgani* Zarudny & Loudon, 1904 - NW Iran and Zagros Mts.

**Descriptive notes.** 14-16 cm; 16-25 g (*hortorum*), 18-22 g (*comminutus*), 19-26 g (*minor*). Male has buff-tinged white forehead and lores, crimson-red crown (usually some pale feather bases showing) bordered by narrow black lines, black nape and hindneck; rest of head, including chin and throat, white or whitish, with black malar stripe expanding on neck side and extending irregularly down to upper breast side; black upperparts, broad white bars on lower mantle and lower scapulars to upper rump, wing-coverts with broad white spots or bars near tips; black flight-feathers broadly barred white; uppertail black, outer feathers white with

2 or 3 dark bars near tip; white underparts with slight buff tinge, breast sides and flanks with thin black streaks, undertail-coverts usually spotted black; short bill chisel-tipped, dark grey to blackish, paler base of lower mandible; iris red-brown or brownish; legs greenish-grey. Female lacks red on head, has white or buffish-white forecrown, black crown sides and hindcrown. Juvenile duller than adult, black areas tinged brown, pale forehead patch obscured by darker tips, heavier but duller and less defined streaks below, male with greyish-mottled pinkish-red forecrown, female with pale forecrown obscured by dark tips and usually a few reddish tips. Races differ in size, plumage darkness and pattern, but variation often clinal and many intermediates: *kamtschakensis* is largest, long-winged, has proportionately longer bill than nominate, much more white above, almost unmarked white outer tail, few or no streaks below; *amurensis* is very like nominate, but narrower white bars above, slightly greyer and usually more streaked below; *hortorum* has slightly less white on back than nominate, outer rectrices more barred, buff or light brown face and underparts, throat sometimes tinged pink, flanks more heavily streaked; *buturlini* is darker than previous, more heavily streaked below; *comminutus* resembles previous, but slightly smaller, with much fainter streaks below; *ledouci* is also dark, but pale areas of head to breast somewhat darker buff-brown, often heavier streaking below, may show some black behind ear-coverts, usually has all-black bill; *danfordi* is similarly dark below, sometimes brown-tinged, has black band from hindcrown around rear ear-coverts; *colchicus* is like previous, but has more white above, black band behind ear-coverts sometimes broken; *quadrifasciatus* is small, short-billed, has less white above, sometimes hint of black band joining malar with nape, outer rectrices heavily barred black, pale areas buff-brown, flanks heavily dark-streaked and sometimes barred; *morgani* is distinctive, has very long and narrow bill, broad black band behind ear-coverts, buff face, deep buffish-brown upper breast (and sometimes chin and throat) contrasting with white rest of underparts, very sharp black streaks on breast and flanks. VOICE. Commonest is series of notes, "gee-geegeegee" or longer; single "gig" and various other calls rarely heard. Both sexes drum, characteristic long high-pitched rolls at 14-19 per minute, often interspersed with call series at height of courtship.

**Habitat.** Temperate and boreal deciduous woodland in lowlands. Open forest with softwood deciduous trees in vicinity of lakes or rivers are preferred; also forest edge, and in parks, orchards and gardens. Requires good number of thin snags, as in old stands or in riparian woodland. Restricted to cork-oak forest, especially with *Quercus suber*, in N Africa. Lowlands and foothills to 850 m, locally to 1260 m, in Europe; at higher elevations in Asia, to 1400-2000 m in Caucasus, 1700 m in Altai Mts, and 1400 m in Mongolia; to 1300 m in N Africa.

**Food and Feeding.** Small insects comprise main bulk of diet. In summer, mostly caterpillars, aphids, ants, beetles, and other surface-dwelling arthropods, including Diptera and spiders; even small snails (*Discus*) taken. In winter, wood-boring larvae (e.g. Buprestidae, Cerambycidae, Curculionidae) and those living under the bark (e.g. Scolytidae, Ipidae) become important. Ants more important in S parts of range. Eats very little vegetable matter, but occasionally takes fruit and berries, and seeds at feeders. Generally forages singly; may join mixed flocks, especially with tits (*Paridae*), outside breeding season. Forages quietly in upper stratum or in dense vegetation. Prefers to seek food from (vertical) twigs 1-3 cm in diameter in the canopy, rarely on the trunk or base of large trees; descends to lower levels mainly to visit bushes and plant stalks, latter including particularly reed (*Phragmites*), occasionally corn. Foraging techniques include gleaning, hammering, pecking series to dislodge large pieces of bark, and probing; gleaning predominates when foraging for nestling food. Also makes aerial sallies for insects, and visits sap holes made by other woodpecker species.

**Breeding.** Laying Apr to mid-May, to Jun in N. Generally monogamous, pair-bond may extend over several years; also, study in S Sweden found almost 10% of females polyandrous, c. 3% of males polygynous. Courtship from Feb, most conspicuous displays wing-spreading and tail-spreading, characteristic flutter-aerial display, and gliding flight with wings held well above back. Nest-hole excavated by both sexes, male often taking greater share, work lasting 2-4 weeks, sometimes as few as 6 days; at 0-4-20 m, usually below 8 m, in soft wood of dead or decaying trunk, stump or underside of a branch, hole entrance 3-3.5 cm, cavity depth 10-18 cm; nestbox used rarely; territory often small. Clutch 5-6 eggs, rarely 3 or up to 9; incubation by both sexes, male often doing more, period 10-12 days; chicks fed by both parents, fledging period 18-21 days, rarely up to 23 days; juveniles cared for by parents for a further 1-2 weeks. Success variable; in study in S Sweden, 34% of breeding attempts failed to produce fledglings, and polyandrous females c. 40% more successful than monogamous ones. First breeding at 1 year.

**Movements.** Resident in most of range. N populations partly migratory; movements often eruptive in nature, in parallel with movements of *D. major*. Autumn migration mainly late Aug to Nov; N European birds may reach C Europe and Black Sea.

**Status and Conservation.** Not globally threatened. Fairly common to scarce in most of range; nowhere very common; scarce in N Africa. European population estimated at c. 195,000-240,000 pairs, of which 40,000-60,000 in Belarus, c. 30,000-50,000 in Germany, 20,000-40,000 in Poland, 20,000-30,000 in Hungary. Densities generally low, e.g. 2-3 pairs/100 ha in primeval deciduous forest in Poland, and elsewhere in Europe only 0-0.6-1.6 pairs/km<sup>2</sup>. Appears to have declined in many parts of Europe, largely as a result of loss of deciduous habitats, especially riverine forest and old orchards, which were previously used extensively. Responds negatively to forest fragmentation and admixture of conifers. Main conservation measure required is to ensure that adequate suitable habitat remains for this species.

## 95. Brown-fronted Woodpecker

*Dendrocopos auriceps*

French: Pic à tête jaune

German: Braunstirnspecht

Spanish: Pico Frentipardo

Other common names: Brown-fronted Pied Woodpecker

**Taxonomy.** *Picus auriceps* Vigors, 1831, Himalayas.

Genus sometimes merged into *Picoides*. Size decreases clinally from W to E, but no grounds for naming of geographical races. Some variation in the nape colour of females, but few details; further study required. Monotypic.

**Distribution.** N Baluchistan, and W Himalayas from NE Afghanistan (Nuristan) E to N India and E Nepal.

**Descriptive notes.** 19-20 cm; 37-50 g. Male has dull brown to yellow-brown forehead and forecrown, yellower mid-crown, orange-red nape patch, black hindneck; rest of head white, grey-brown feather tips forming darker patch on ear-coverts, narrow brown-grey malar stripe becoming broader and black at rear, continuing to upper breast side; white chin and throat tinged brown or grey; black upperparts barred white on mantle and back, wing-coverts broadly tipped white; brownish-black flight-feathers barred white; uppertail black, outer feathers barred white; white below, lower breast and flanks tinged yellow, becoming pink or

orange on central belly and undertail-coverts, broad black streaks on breast becoming paler and narrower on lower underparts, belly sometimes plain; medium-long bill slightly chisel-tipped, culmen barely curved, slate-grey to bluish, paler base of lower mandible; iris red-brown to red; legs grey-green to slate-grey. Distinguished from *D. macei* by shorter bill, yellow crown, and heavier streaking on white underparts; from *D. maharattensis* also by slightly larger size, duller crown colour, darker malar, and red undertail-coverts. Female differs from male in head pattern, has crown duller yellow, occasionally with hint of orange, sometimes greener, this colour continuing to nape, also duller red eyes. Juvenile duller than adult, with browner ear-coverts, is greyer below with paler pink vent, both sexes with crown as adult female's or sometimes streaked, male with trace of red in hindcrown, female with orange or yellow. VOICE. Call "chick" or "peek", more squeaky than that of *D. himalayensis*, resembling call of *D. hyperythrus*; also "chitter-chitter-chitter-r-r-rh" or "cheek-cheek-cheek-rrrr", recalling a kingfisher (Alcedinidae). Drums frequently in breeding season.

**Habitat.** Coniferous and pine-oak forest, and montane dry deciduous forest; also park-like woodland and secondary growth. In Pakistan mainly in subtropical pine belt (*Pinus roxburghii*, *P. longifolia*), but also visits *P. gerardiana* forest and cedar (*Cedrus*) stands. Breeds to at least 2100 m in Afghanistan; at 900-1800 m in Pakistan, with few to 3000 m; 1000-2400 m, less commonly to 2950 m, in Nepal. Generally replaced by *D. himalayensis* at higher altitudes.

**Food and Feeding.** Insects and their larvae, mainly lepidopteran caterpillars, grubs. Commonly takes vegetable matter, including fruits, berries and pine seeds; possibly sap. Forages singly or in pairs; often joins mixed flocks of tits (*Paridae*) and minivets (*Pericorotus*). Foraging mostly confined to trees and bushes, rarely visits ground. Main techniques gleaning and probing; also hammers.

On following pages: 96. Fulvous-breasted Woodpecker (*Dendrocopos macei*); 97. Stripe-breasted Woodpecker (*Dendrocopos atratus*); 98. Yellow-crowned Woodpecker (*Dendrocopos maharattensis*); 99. Arabian Woodpecker (*Dendrocopos doriae*); 100. Rufous-bellied Woodpecker (*Dendrocopos hyperythrus*); 101. Crimson-breasted Woodpecker (*Dendrocopos cathpharius*).

**Breeding.** Season Apr-Jul. Nest-hole excavated at 2-12 m, mostly below 8 m, in dead trunk or in underside of large branch of pine, Himalayan elm (*Ulmus wallichiana*) or other tall tree. Clutch 3-5 eggs, usually 4; incubation and fledging periods not recorded; chicks fed by both parents.

**Movements.** Descends to lower altitudes in winter.

**Status and Conservation.** Not globally threatened. Locally common throughout range. No known threats. Research required to determine details of its breeding.

**Bibliography.** Ali & Ripley (1983), Bates & Lowther (1952), Biswas (1961a), Christison (1942), Delacour (1951a), Diesselhorst (1968), Fulton (1904), Grimmett *et al.* (1998, 2000), Hùe & Ètchécopar (1970), Inskipp, C. (1989), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Kazmierczak (2000), Mason & Lefroy (1912), Mohan (1997), Proud (1958), Raja *et al.* (1999), Rand & Fleming (1956), Ripley (1982), Roberts (1991), Shrestha (2000), Whitehead (1911), Winkler & Short (1978).

## 96. Fulvous-breasted Woodpecker

### *Dendrocopos macei*

**French:** Pic de Macé

**German:** Isabellbrustspecht

**Spanish:** Pico de Macé

**Other common names:** Fulvous-breasted/Spotted-breasted Pied Woodpecker, Streak-bellied Woodpecker

**Taxonomy.** *Picus Macei* Vieillot, 1818, Bengal.

Genus sometimes merged into *Picoides*. Forms a superspecies with *D. atratus*. E races *analis*, *longipennis* and *andamanensis* have sometimes been treated as forming a separate species. Birds from W Javan hills described as race *montis*, but inseparable from *analis*. Five subspecies recognized.

**Subspecies and Distribution.**

*D. m. westermanni* (Blyth, 1870) - N Pakistan (Margalla Hills), NW India (Himachal Pradesh) and W Nepal.

*D. m. macei* (Vieillot, 1818) - C Nepal E to N Myanmar, and S in E peninsular India to Orissa and NE Andhra Pradesh.

*D. m. andamanensis* (Blyth, 1859) - Andaman Is.

*D. m. longipennis* Hesse, 1912 - S Myanmar, NW, W & C Thailand, and C Laos and Annam S to Cambodia and Cochinchina.

*D. m. analis* (Bonaparte, 1850) - Java and Bali; probably also S Sumatra.

**Descriptive notes.** 18-19 cm; 23-38 g (*macei*). Male has buffish lower forehead, red upper forehead to nape with black feather bases showing, white lores, face and sides of neck tinged pale buffish, especially on ear-coverts, black malar stripe expanding at rear and continuing just on to upper breast side; very pale buffish-white chin and throat; black hindneck and upperparts, broad white bars from mantle to upper rump, wing-coverts broadly tipped white; black flight-feathers barred white; uppertail black, outer 1 or 2 feather pairs barred white; light buffish-brown below, breast occasionally tinged reddish, belly and flanks sometimes

browner, breast sides and flanks streaked blackish, lower flanks and belly sometimes barred, central lower belly to undertail-coverts unmarked red; long bill straight, chisel-tipped, blackish-grey, paler base; iris red-brown, orbital skin grey; legs grey-green to greenish-slate. Distinguished from *D. auriceps* by much longer bill, fully red crown, darker underparts with less heavy streaking; from *D. atratus* by slightly smaller size, less heavy streaking below. Female has entire top of head black. Juvenile duller above and below than adult, has only small area of pink (not red) on undertail-coverts, both sexes with some red in crown centre, much less on female. Race *westermanni* has longer bill, wing and tail than nominate, slightly darker throat contrasting less with breast; *analis* has black nape, buff-brown ear-coverts, fully barred tail, white throat, paler yellow-buff tinge below, breast with small blackish spots, reduced markings on belly and flanks, pale pink undertail-coverts; *longipennis* as previous, but paler below with markings more prominent, broader spots and streaks on breast forming necklace, thin bars on flanks, deeper red-pink undertail-coverts; *andamanensis* distinctive, has pale bill, black-streaked face, fully barred tail, white throat, large rounded or heart-shaped spots on breast, barred upper belly and flanks, female with brown, not black, crown. **VOICE.** Call "chick", sharper than that of *D. canicapillus*, less sharp and less loud than *D. atratus*, given singly or in series; also "pik-pik" or "chik-it-chik-it"; rattle comprising call note and a series of slightly lower "pit" notes, terminating with call note, slower than similar vocalization of *D. canicapillus*. Drums in weak, short rolls.

**Habitat.** In S Asian lowlands and foothills prefers open forest, edge, secondary forest, open country with scattered trees, plantations and gardens; also found in bamboo stands, and in scattered trees and larger bushes along dry riverbeds. In Himalayas, occurs in tall deciduous stands, especially mixed *Bombax-Ficus* woods; also tropical dry deciduous scrub in Pakistan. Generally found below 1200 m in SE Asia, and mostly below 600 m; present up to 2800 m in Himalayas and Greater Sundas.

**Food and Feeding.** Ants, a variety of other insects, larvae (usually large ones), also small scorpions (Scorpiones); berries and fruits also taken. Occurs singly or in pairs, or in family parties, also in mixed-species flocks. Favours tall trees, including isolated ones in open areas near forest. Forages on trunks and larger branches, also well up under the crown and among crown foliage on small branches and large twigs; rarely at lower levels (except in Andamans), or on the ground when seeking ants. Feeding techniques include gleaning, probing and strong pecks and hammering; also prises off bark.

**Breeding.** Jan-May, sometimes to Jun, in Indian Subcontinent; Dec-Mar. less commonly to Jun, in SE Asia; mostly between Apr and Oct, rarely Jan, in Java. Display with crest-raising, swinging movements, and others, also fluttering aerial display. Nest-hole excavated by both sexes, at 1-3 m, sometimes higher, in branch (often on underside) of free-standing tree, or in bamboo, or in fence post or palm stub in open ground at edge of forest. Clutch 2-5 eggs, usually 3; incubation and brood-feeding by both parents, respective periods not documented.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Local and rare in Pakistan, but possibly more common than believed; common to frequent in Nepal, common in India and Bangladesh, uncommon in Bhutan; uncommon to fairly common in Myanmar and SE Asia; fairly common in Java and Bali. Occurs in several protected areas, e.g. Corbett, Dibru Saikhowa and Kaziranga National Parks (India), Doi Inthanon National Park (Thailand), Balaun National Park (Java) and Bali Barat National Park (Bali).

**Bibliography.** Ali & Ripley (1983), Ali *et al.* (1996), Andrew (1992), van Balen (1999), Barker *et al.* (1999), Biswas (1961a), Deignan (1945), Delacour (1951a, 1951b), Duckworth *et al.* (1999), Fleming & Traylor (1968),

(1989), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), King & Rappole (2001), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Philipps (1993, 2000), van Marie & Voous (1988), Mees (1996), Proud (1952, 1958), Rattray (1905), Riley (1938), Ripley (1982), Roberts (1991, 1996), Robson (2000), Sargeant (1997), Short (1973a), Smythies (1986), Stresemann (1921a), Tykader (1984), Tymstra *et al.* (1997), Wexler (1996), White & Bruce (1986), Winkler & Short (1978), Yoganand & Davidar (2000).

## 97. Stripe-breasted Woodpecker

### *Dendrocopos atratus*

**French:** Pic à poitrine rayée

**German:** Streifenbrustspecht

**Spanish:** Pico Estriado

**Other common names:** Stripe-breasted Pied Woodpecker

**Taxonomy.** *Dryobates atratus* Blyth, 1849, Tenasserim.

Genus sometimes merged into *Picoides*. Forms a superspecies with *D. macei*. Birds from Vietnam have sometimes been separated as race *vietnamensis*, but available evidence suggests they are not clearly distinguishable; further study required. Monotypic.

**Distribution.** NE Indian hills (Meghalaya, Manipur, Mizoram), and possibly also C & SE Bangladesh, to W, S & E Myanmar and SW China (W & S Yunnan), and S to W & C Thailand, Cambodia, S Laos and SC Annam.

**Descriptive notes.** 21-22 cm; 42-52 g. Male has whitish nasal tufts beneath dark lower forehead, bright red upper forehead to nape (rarely some admixed yellow) with usually some black streaks, black hindneck; rest of head and neck white, usually with a few thin black streaks, black malar stripe expanding on side of neck and extending to upper breast side, whitish throat lightly streaked dark; upperparts black, broad white bars from lower mantle to upper rump, wing-coverts with large white sub-terminal spots (much smaller on lesser coverts); black flight-feathers barred white; uppertail black, white bars on outer 2, sometimes 3,

feather pairs; pale greyish-yellow below, belly yellow, very broad long black streaks over entire area down to lower belly (occasionally absent on central belly), lower flanks slightly barred, undertail-coverts tipped bright red; long bill straight, chisel-tipped, horn-brown to dark grey or sometimes greenish, paler base; iris brown to brown-red; legs grey, often tinged blue or greenish. Differs from *D. macei* mainly in larger size, stronger bill, much heavier markings below. Female lacks red on head, has crown and nape entirely black. Juvenile duller than adult, greyer below with fewer but more obscure streaks, vent more orange, male with dark red on crown, female with a few red-tipped feathers in mid-crown. **VOICE.** Explosive "chick", and whinnying rattle call. Probably drums. **Habitat.** Open oak (*Quercus*) and pine (*Pinus*) woodland in hill evergreen forest; pine forest preferred, but edges of open broadleaved forest also occupied. Also occurs in cultivated areas and in clearings with scattered trees. Between 800 m and 2200 m, occasionally higher; to 1500 m in NE Indian hills.

**Food and Feeding.** Insects, particularly beetle larvae and ants. Seen singly, in pairs or in family parties. Forages mostly at middle to upper levels, but sometimes at lower levels. Pecking and hammering seem to be rather important feeding modes.

**Breeding.** Mar-May in India and Apr-May in Myanmar; Feb-May elsewhere. Nest-hole excavated at up to 4 m in stump, or much higher, to 20 m, in tree. Clutch 4-5 eggs. No information on incubation and fledging periods; few data, but one record of fledglings accompanied by parents for at least 10 days.

**Movements.** None recorded.

**Status and Conservation.** Not globally threatened. Status in India uncertain, but appears to be uncommon; in Bangladesh, possibly rare to scarce, but no recent information. Rare in China (Yunnan). Fairly common but rather local in SE Asia. Occurs in Doi Inthanon and Nam Nao National Parks (Thailand).

**Bibliography.** Ali & Ripley (1983), Chazee (1994), Deignan (1945), Delacour (1951a), Delacour & Jabouille (1940), Duckworth *et al.* (1999), Evans & Timmins (1998), Grimmett *et al.* (1998), Inskipp, C. *et al.* (1999), Inskipp, T. *et al.* (1996), Kazmierczak (2000), Khan (1982), Lekagul & Round (1991), MacKinnon & Philipps (2000), Riley (1938), Ripley (1982), Robson (2000), Smythies (1986), Winkler & Short (1978), Zhao Zhengjie (1995), Zusi & Marshall (1970).

## 98. Yellow-crowned Woodpecker

### *Dendrocopos mahrattensis*

**French:** Pic mahratte

**German:** Gelbscheitelspecht

**Spanish:** Pico Mahratta

**Other common names:** Yellow-fronted/Mahratta Woodpecker/Pied Woodpecker

**Taxonomy.** *Picus Mahrattensis* Latham, 1801, Mahratta country, south-west India.

Genus sometimes merged into *Picoides*. Most closely related to the *D. macei* superspecies. Variation mostly clinal, and named races *aurocristatus* (N Myanmar) and *koelzi* (NW Sri Lanka) are thus unacceptable. Two subspecies recognized.

**Subspecies and Distribution.**

*D. m. pallascens* Biswas, 1951 - E Pakistan (E of R Indus) and N & NW India.

*D. m. mahrattensis* (Latham, 1801) - most of India E to Assam, Sri Lanka, and W, C & S Myanmar, E Cambodia, S Laos and S Annam; formerly also WC Thailand (extinct).

**Descriptive notes.** 17-18 cm; 28-46 g. Male has golden-yellow forehead and forecrown, becoming red on hindcrown and nape, dark brown hindneck; white sides of head tinged or streaked brownish below eye and on ear-coverts; rich brown rear malar stripe continuing upwards behind ear-coverts and down on to upper breast side; white chin and throat sometimes tinged brown; blackish-brown or black upperparts, feathers broadly edged white near tips, rump largely white; white uppertail-coverts with black central wedge; wing-coverts tipped white, flight-feathers barred white; uppertail dark brown-black, fully barred white; whitish below, streaked brown or blackish, streaks often lacking or indistinct in breast centre but broad on breast sides and upper flanks, belly centre orange-red; long bill fairly straight, slightly chisel-tipped, slate-grey to horn, paler base of lower mandible; iris brown to red-brown; legs blue-grey. Distinguished from similar *D. auriceps* by less barred upperparts, fainter incomplete malar, fully barred tail, orange belly patch, and white undertail-coverts. Female has yellowish crown with no red or with just few red tips, brownish nape. Juvenile duller than adult, more brownish above, with streaks below more dif-

bordering roadsides or watercourses; also found in cultivations and gardens. Visits remnant semi-evergreen patches near coast in W India. Shows distinct preference for the abundant big *Euphorbia antiquorum* trees in dry districts of Sri Lanka. Below 1000 m in most of range; only occasionally higher, to 1700 m in Nepal, to 2000 m in S India.

**Food and Feeding.** Bark-dwelling insects, also fruits and nectar. In particular, caterpillars (Geometridae), grubs (Elateridae, Curculionidae, Buprestidae) and dragonflies (Odonata) reported. Forages singly or in pairs, members of which keep in loose vocal contact; also joins mixed-species flocks. Stays mostly in crown of trees and on trunks, comes down to the ground rarely; regularly clings upside-down. Excavates bark and dead wood for insect larvae; observed pecking holes in dry pods of *Cassia fistula* to extract insect larvae.

**Breeding.** Feb-Jul, also Dec, in Indian Subcontinent; Feb-Apr in SE Asia. Nest-hole excavated at 1-10 m in dead section of live tree, often on underside of a sloping branch; usurpation of hole by *Dinopium benghalense* recorded. Clutch 3 eggs; both parents incubate and both feed chicks; incubation period 13 days, fledging period not documented; fledglings may stay with parents until onset of next breeding cycle.

**Movements.** None recorded.

**Status and Conservation.** Not globally threatened. Frequent in Pakistan, locally common in India, uncommon in Nepal, common in SE Sri Lanka; no recent records from Bangladesh; rare to uncommon in SE Asia. Occurs in several protected areas, e.g. Keoladeo Ghana, Ranthambore and Mudumalai National Parks and Peechi-Vazhani Wildlife Sanctuary (India) and Uda Walawe, Yala and Bundala National Parks (Sri Lanka).

**Bibliography.** Ali (1996), Ali & Ripley (1983), Betts (1934), Biswas (1951), Delacour (1951a), Delacour & Jabouille (1940), Duckworth *et al.* (1999), Eates (1937), Gokula & Vijayan (1997), Grimmett *et al.* (1998, 2000), Harrison (1999), Harvey (1990), Henry (1998), Inskipp, C. (1989), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Javed & Rahmani (1998), Kalsi (1998), Kazmierczak (2000), King & Rappole (2001), Lainer (1999), Lamsfuss (1998), Lekagul & Round (1991), Mason & Lefroy (1912), Morioka & Sakane (1981), Mukherjee (1995), Phillips (1978), Ripley (1982), Roberts (1991), Robson (2000), Round (1988), Santharam (1998a, 1998b, 1998c), Shrestha (2000), Smythies (1986), Thewlis *et al.* (1998), Whitehead (1911), Winkler & Short (1978).

## 99. Arabian Woodpecker

### *Dendrocopos dorae*

**French:** Pic d'Arabie

**German:** Araberspecht

**Spanish:** Pico Árabe

**Taxonomy.** *Desertipicus dorae* Bates and Kinnear, 1935, Ukadh, Taif-Mecca road, Arabia.

Genus sometimes merged into *Picoides*. Relationships unclear; thought most likely to be related to *D. maharattensis* and the *D. macei* superspecies. Monotypic.

**Distribution.** SW Arabian Peninsula, in narrow band from just N of Mecca S to W South Yemen.

brown below, red or orange-red patch on central belly, flanks and lower belly faintly barred brown and white, browner undertail-coverts spotted or barred white; fairly long bill almost straight, chisel-tipped, broad across nostrils, slate-grey to horn, usually paler base of lower mandible; iris whitish or grey-brown; legs grey. Female lacks red on head, tends to be somewhat duller, with less prominent red on belly. Juvenile much as adult, but greyer with some streaking below, belly more pink than red, male with orange-red patch on crown. **VOICE.** Common vocalization "pweek pit-pit-pit-pit-pit-pit-pitpt". Occasionally drums, feebly.

**Habitat.** Inhabits riparian woodland dominated by *Cordia abyssinica*, well-mixed and dense stands of predominantly *Juniperus*, *Olea* and *Nuxia* on mountain slopes; also uses pure stands of *Acacia origina*, and scattered acacias (predominantly *A. iraquensis*) in flat desert areas; also palm and fig groves with adjacent acacias at base of escarpments. Breeds mainly in valleys, on slopes and in highlands at altitudes of 1200-2400 m; occurs from sea-level up to 3000 m outside breeding season.

**Food and Feeding.** Larvae of wood-boring insects, fig wasps, and aphids and other winged insects recorded as adult and nestling food. Ants living in base of acacias possibly important. Tree sap important in winter; may take fruits as well. Usually singly or in pairs. Forages commonly in crown of trees, mostly *Acacia*, on medium to thin branches and twigs, frequently along underside; also descends to ground. Hammers, probes, and occasionally flakes off bark; gleaning is predominant foraging technique in nesting season.

**Breeding.** Mar-May, occasionally from Feb; possibly in Nov in Yemen. Nest excavated mostly at 0.5-6 m up tree trunk or limb in live or dead wood, or at up to 9 m and rarely even 25 m in stump of palm tree. Clutch 3 eggs; incubation by both parents, for period of 11 days; both adults also feed chicks, fledging period c. 22 days; young birds remain in nesting area for at least two months after fledging.

**Movements.** Some seasonal altitudinal movements apparent; found down to lowlands in winter, and in summer at least part of population moves c. 350 m farther upslope.

fuse, belly pinker, eyes brown, bill usually paler, male with some orange-red on crown and often nape, female with a few orange-red feathers in central crown. Race *pallascens* is paler than nominate, has paler head markings, larger white markings above, rump sometimes completely white, streaks below very light brown. **VOICE.** Feeble "peck" or sharp "click, click", also "click-r-r-r-r", "kik-kik-kik-r-r-r-h". Drums.

**Habitat.** Dry to very dry open woodland and desert scrub, including deciduous woodland, second growth, riverine forest, wild olive (*Olea cuspidata*) woodland, plantations, and trees

**Status and Conservation.** **VULNERABLE.** Generally rather uncommon, locally rare. Occurs in Asir National Park and Rayah Reserve (Saudi Arabia). Population small, estimated at fewer than 10,000 individuals, and probably declining. Densities vary from 0.1 to 1.0 adults/km<sup>2</sup>. Following centuries of human colonization and associated activities, this species' woodland habitat has become highly fragmented. Continuing clearance for agriculture and building, and for firewood, often result in removal of large trees required by this woodpecker for its nest-sites; heavy grazing can prevent the regeneration of trees. Although many wooded areas in W Arabia have long been protected from overexploitation, to ensure a source of fodder during drought, traditional management was largely abandoned in latter part of 20th century as it became easier to obtain alternative supplies of feed. Effective conservation measures proposed include designation of additional protected areas, the encouragement of non-intensive, traditional methods of woodland management, and the raising of the profile of this species in its Arabian homeland.

**Bibliography.** Brooks *et al.* (1987), Cornwallis & Porter (1982), Everett (1987), Hansbro & Sargeant (2000), Hollom *et al.* (1988), Jennings, M.C. (1995), Lees-Smith (1986), Newton & Newton (1996), Porter, Christensen & Schiermacker-Hansen (1996), Porter, Martins *et al.* (1996), Rands *et al.* (1987), Stagg (1985), Stanton (1997), Stattersfield & Capper (2000), Varisco *et al.* (1992), Winkler & Short (1978), Winkler *et al.* (1996).

## 100. Rufous-bellied Woodpecker

### *Dendrocopos hyperythrus*

**French:** Pic à ventre fauve

**German:** Braunkehlspecht

**Spanish:** Pico Ventrirrufo

**Other common names:** Rufous-bellied Pied Woodpecker/Sapsucker

**Taxonomy.** *Picus hyperythrus* Vigors, 1831, eastern Himalayas.

Genus sometimes merged into *Picoides*. Relationships within genus somewhat obscure; most likely related to S Asian *D. macei* superspecies and *D. cathpharius*. Variation, particularly in tone of underparts, is considerable, but largely individual. Four subspecies recognized.

**Subspecies and Distribution.**

*D. h. marshalli* (Hartert, 1912) - NE Pakistan, Kashmir and N India.

*D. h. hyperythrus* (Vigors, 1831) - Nepal E to SE Tibet and W & SW China (Sichuan, Yunnan), S to Bangladesh, C Myanmar and NW Thailand.

*D. h. annamensis* (Kloss, 1925) - E Thailand, Cambodia and S Vietnam.

*D. h. subrufinus* (Cabanis & Heine, 1863) - Manchuria and Ussuriland; winters S China.

**Descriptive notes.** 20-25 cm; 40-53 g (*hyperythrus*, *annamensis*), 53-74 g (*marshalli*, *subrufinus*). Male has bright red forehead to nape (in W populations, red often continues behind ear-coverts), nape sometimes tinged orange, often a few black feather bases showing on crown; white lores, forecheeks and thin line over and just behind eye, a few greyish marks in loreal area; whitish malar region with dusky streaks; rest of head rufous-chestnut; entire upperparts black, mantle to upper rump barred white, bars broadest on upper back, wing-coverts and flight-feathers with white spots forming bars; uppertail black, outer 2 feather pairs

barred white; rufous-chestnut continues over underparts, but for pinkish-red lower belly and undertail-coverts, narrow band of black and white bars on lower belly sides and flanks; long bill almost straight, chisel-tipped, black or blackish, lower mandible pale yellow or greener; iris red-brown to pale reddish or deep brown; legs olive to greenish-grey or slaty. Female has black forehead to hindneck with white spots, occasionally a few red feather tips. Juvenile has white-spotted black crown, streaked head, heavily streaked throat, upperparts more spotted than barred, browner wings, brownish underparts barred black and white, paler pinkish vent, darker brown eyes, male with many orange-red tips on crown, female with fewer; adult plumage acquired gradually, traces of juvenile plumage still evident in winter. Race *marshalli* is larger than nominate, red on head of male extends over entire nape, hindneck and rear part of sides of neck; *subrufinus* is on average largest, and paler, more rufous-buff, below; *annamensis* resembles previous, but is somewhat smaller, with relatively long bill. **VOICE.** Call "chit-chit-chit-r-r-r-r-h"; fast "ptkitititititit" in alarm. Both sexes drum in breeding season, rolls fading towards end.

**Habitat.** Broadleaved forest and mixed and coniferous forest. In Pakistan, prefers deciduous forest with Himalayan poplar (*Populus ciliata*) and false dogwood (*Cornus macrophylla*); farther E, found in evergreen montane forest and cloudforest, in oak (*Quercus*), chestnut (*Castanopsis*), silver fir (*Abies*) and pine (*Pinus*) forests, in mixed forest and in rhododendron. Occurs in oak and alder (*Alnus*) stands in N Myanmar, and open woodland of oak, pine and dry dipterocarp trees elsewhere in SE Asia. Occurs at 1500-2000 m in Pakistan, and 2100-4100 m in Nepal and Sikkim; in NW Myanmar most common at 2000-2800 m, and in other parts of SE Asia ranges between 500 m and 1200 m; to 4300 m in China.

**Food and Feeding.** Insects, and vegetable matter. Ants can constitute more than 60% of diet; beetles (Carabidae), Orthoptera, Lepidoptera and caterpillars, and other small insects also recorded. Feeds on sap in spring. Often singly; may associate with flocks of small insectivorous birds outside breeding season. Forages on tree trunks in the canopy; probes frequently, also hammers and gleans. Sometimes catches prey on the wing. Creates sap wells by drilling dense rows of 8-10 small holes girdling trunks of various tree species.

**Breeding.** Apr-May in Nepal and India; Mar-May in SE Asia. Nest a typical woodpecker hole excavated at 5-6 m in trunk of tree. Clutch 4 or 5 eggs; incubation and fledging periods not documented; both sexes care for chicks.

**Movements.** NE populations (*subrufinus*) migratory, passing through C China in May and again in Aug-Sept, and wintering in S & SE China; vagrant in Korea (last record 1933). Altitudinal movements in Tibet, moving down to 1500 m after breeding; possibly some similar movements in Nepal, down to 2000 m outside breeding season.

**Status and Conservation.** Not globally threatened. Rather uncommon to scarce in most of range. Possibly locally more common in N India and Nepal, common in Bhutan; no recent records from Bangladesh. Uncommon to scarce in China and Ussuriland. Has disappeared from some parts of range since 1960's; in Pakistan, loss of deciduous trees through cutting for animal forage has resulted in some forests becoming dominated by coniferous stands, unsuitable for this species.

# 101. Crimson-breasted Woodpecker

## *Dendrocopos cathpharius*

**French:** Pic à plastron rouge **German:** Rotbrustspecht **Spanish:** Pico Pechirrojo  
**Other common names:** (Small) Crimson-breasted Pied Woodpecker, Lesser Pied Woodpecker

**Taxonomy.** *Picus* (*Dendrocopos*) [sic] *cathpharius* Blyth, 1843, Darjeeling.  
Genus sometimes merged into *Picooides*. Most closely related to *D. darjellensis*, and probably more distantly to the *D. macei* superspecies. Six subspecies recognized.

### Subspecies and Distribution.

- D. c. cathpharius* (Blyth, 1843) - WC Nepal E to Arunachal Pradesh.
- D. c. ludlowi* Vaurie, 1959 - SE Tibet (S Tsangpo Valley).
- D. c. pyrrhorthorax* (Hume, 1881) - NE India S of R Brahmaputra (Meghalaya, Nagaland, Manipur, Mizoram) and W Myanmar (W of R Chindwin).
- D. c. pernyi* (J. Verreaux, 1867) - WC & SW China (SW Gansu, N & E Sichuan, NW Yunnan).
- D. c. innixus* (Bangs & J. L. Peters, 1928) - C China (S Shaanxi, Hubei).
- D. c. tenebrosus* (Rothschild, 1926) - N, C & E Myanmar, C & S Yunnan, NW Thailand, N Laos and W Tonkin.

**Descriptive notes.** 17-19 cm; 23-35 g. Male has buffish-white forehead with indistinct dark central line, black crown, red nape, hindneck and rear part of sides of neck; white lores and side of head, ear-coverts with faint buff tinge and sometimes very faint dark streaks; black malar stripe joining black patch on side of neck and extending down to breast side; white chin, pale buff throat; black upperparts and wings, inner wing-coverts mainly white, flight-feathers with small white spots forming narrow bars; uppertail black, outer 3 feather pairs barred whitish; pale buffish below, more yellowish on belly and flanks, small ill-defined patch of orange-red in breast centre (red can be lacking), breast broadly streaked black, streaks thinner from lower breast and mid-flanks, undertail-coverts streaked black and broadly tipped orange-red; relatively short bill grey to blue-grey, lower mandible very pale grey to whitish; iris brown to red-brown, orbital skin slate-grey or paler; legs dull grey to grey-green. Female has red on head replaced by black. Juvenile much as adult but darker and duller below, no red on breast, red of vent much paler or absent, male with orange-red from mid-crown to nape, female with smaller area of orange-red. Race *ludlowi* is slightly bigger than nomi-

nate, has more red on breast; *pyrrhorthorax* is much paler on face and below, less streaked below, with prominent red patch on breast, redder undertail-coverts; *pernyi* is larger, has red on head restricted to nape, less white in wing, red breast patch bordered by broad black band, redder undertail-coverts; *innixus* resembles previous, but much paler below, black breastband narrower, lower underparts unstreaked or nearly so; *tenebrosus* is similar to last but smaller, has slightly more black on breast, much heavier streaking. **VOICE:** Loud monotonous "chip" or "tchick"; also very short, fast descending rattle. Drums.

**Habitat.** Broadleaved evergreen and deciduous forest with oaks (*Quercus*), rhododendron and chestnut (*Castanopsis*), at higher elevations. At 700-3000 m, occasionally to 3900 m, but mostly 1200-2800 m; occurs above 1400 m in Thailand, and is most common above 1500 m in Nepal.

**Food and Feeding.** Insects and their larvae; nectar. Usually found singly. Often forages in lower parts of trees and on bushes; prefers dead trees. Frequently hammers.

**Breeding.** Apr-May in W of range. Nest-hole in tree, but no details known. Clutch 2-4 eggs. No other information.

**Movements.** Some altitudinal movement seem possible, but no details available.

**Status and Conservation.** Not globally threatened. Generally uncommon throughout range. Frequent in Nepal, Bhutan and NE India; rare in China; scarce to uncommon elsewhere. Relatively poorly known; research required to determine details of its ecology and breeding. Present in Jiuzhaigou Reserve (China).

**Bibliography.** Ali & Ripley (1983), Ali *et al.* (1996), Bishop (1999b), Choudhury (2001), Deignan (1945), Delacour (1951a), Delacour & Jabouille (1940), Duckworth *et al.* (1999), Étchécopar & Hùe (1978), Grimmett *et al.* (1998, 2000), Inskipp, C. (1989), Inskipp, C. & Inskipp (1991), Inskipp, C. *et al.* (1999), Inskipp, T. *et al.* (1996), Lekagul & Round (1991), MacKinnon & Philipps (2000), Ripley (1982), Robson (2000), Robson *et al.* (1998), Round (1988), Short (1973d), Shrestha (2000), Smythies (1986), Thewlis *et al.* (1998), Tymstra *et al.* (1997), Vaurie (1972), Winkler & Short (1978), Zhao Zhengjie (1995).

## 102. Darjeeling Woodpecker

*Dendrocopos darjellensis*

**French:** Pic de Darjiling      **German:** Darjeelingspecht      **Spanish:** Pico de Darjeeling  
**Other common names:** Darjeeling Pied Woodpecker, Brown-throated Woodpecker

**Taxonomy.** *Picus* (*Dendrocopos*) [sic] *darjellensis* Blyth, 1845, Darjeeling and Nepal. Genus sometimes merged into *Picoides*. Related to *D. cathpharius*; other possible relationships require clarification. NE populations average slightly smaller; birds from W China thus described as race *desmursi*, but variation is clinal in nature. Monotypic.

**Distribution.** WC Nepal and S & SE Tibet E to hills of NE India, N & W Myanmar, W & SW China (S Sichuan, W Yunnan) and N Vietnam (NW Tonkin).

**Descriptive notes.** 25 cm; 61-87 g. Male has whitish lower forehead, black upper forehead and crown, narrow red nape patch, black hindneck; white lores, white sides of head tinged buff (sometimes strongly), golden-yellow to deep orange-buff sides of neck; black malar stripe extending to lower rear ear-coverts and down to sides of upper breast; black upperparts, wings sometimes browner, inner coverts largely white, flight-feathers narrowly barred white; uppertail black, outer 1-3 feather pairs barred white to pale buff; chin to upper breast brownish-buff to buff-brown, paler on lower breast, more yellow on flanks and belly, breast sides and lower breast

with heavy black streaking, flanks and belly often more barred, undertail-coverts pinkish-red; long straight bill dark grey to blackish, pale grey lower mandible with greener or ivory-coloured base; iris red to red-brown, orbital skin slaty-grey; legs grey-green. Female has red of nape replaced by black. Juvenile as adult, but lacks golden patch on neck, is duller below with streaked throat, more barred belly and flanks, duller paler red on undertail-coverts, eyes dark brown, male with dull red crown, female usually with small red central patch or red tips but red may be lacking. **Voice.** Single "tsik" calls, as fast series in alarm; also trill-like rattle. Drums frequently in breeding season.

**Habitat.** High-elevation forest, cloudforest with moss-covered trees, open woodland; also evergreen and coniferous forest, and rhododendron woods. Rarely below 1500 m in SE Asia; mainly 2500-3500 m in Nepal, to almost 4000 m in Sikkim, Tibet and China.

**Food and Feeding.** Larvae of wood-boring insects; also adults, larvae and pupae of other insects. Usually forages singly or in pairs, which keep loose contact; will also join mixed-species flocks. Exploits all levels of habitat, visiting fallen logs, tree trunks and canopy. Mossy and dead surfaces carefully inspected, debris removed. Forceful pecking is rather common technique, and also uses gleaning and probing.

**Breeding.** Apr-May in W of range, sometimes to Jun; first nestlings in May. Moderate crest-raising is only visual display so far described. Nest-hole excavated at 1-2 m in tree. Clutch 2-4 eggs; incubation and fledging periods not documented; chicks fed by both parents.

**Movements.** Not well known; some altitudinal movements in Tibet and China, but some may remain at high elevations even in non-breeding season.

**Status and Conservation.** Not globally threatened. Fairly common in Nepal, locally fairly common in India, common in Bhutan; uncommon in Tibet and China; uncommon in Myanmar and Tonkin. Rather poorly known species, appears to be sparsely distributed throughout range. More study required on its ecology and breeding behaviour.

**Bibliography.** Ali & Ripley (1983), Ali *et al.* (1996), Choudhury (2001), Delacour & Jabouille (1940), Diesselhorst (1968), Étchécopar & Hue (1978), Grinnett *et al.* (1998, 2000), Inskipp, C. (1989), Inskipp, C. & Inskipp (1991, 1993, 1998), Inskipp, C. *et al.* (1999), Inskipp, T. *et al.* (1996), Kazmierczak (2000), Ludlow (1937), MacKinnon & Philipps (2000), Martens & Eck (1995), Ripley (1982), Robson (2000), Short (1973d), Shrestha (2000), Smythies (1986), Stanford & Mayr (1941), Stevens (1925), Tymstra *et al.* (1997), Vaurie (1972), Winkler & Short (1978), Zhao Zhengjie (1995).

## 103. Middle Spotted Woodpecker

*Dendrocopos medius*

**French:** Pic mar      **German:** Mittelspecht      **Spanish:** Pico Mediano

**Taxonomy.** *Picus medius* Linnaeus, 1758, Sweden.

Genus sometimes merged into *Picoides*. Superficial similarity to *D. leucotos* may suggest possible relationship, although this not supported by available genetic data; may be related to *D. macei* superspecies, but little evidence; more study required. Variation is largely clinal, e.g. nominate race becoming darker with flank streaking more pronounced towards S, and races rather poorly differentiated; other named races are *liliana* (NW Spain), *splendidior* (SE Europe to Greece and Turkey) and *laubmanni* (S Transcaucasia), all regarded as unacceptable. Four subspecies recognized.

**Subspecies and Distribution.**

*D. m. medius* (Linnaeus, 1758) - NW Spain and France NE to S Sweden (recently extinct), Estonia, W Russia and Ukraine, and SE to Italy and the Balkans.

*D. m. caucasicus* (Bianchi, 1904) - N Turkey, Caucasus and Transcaucasia; probably this race in NW Iran.

*D. m. anatoliae* (Hartert, 1912) - W & S Asia Minor.

*D. m. sanctijohannis* (Blanford, 1873) - Zagros Mts in SW Iran.

**Descriptive notes.** 20-22 cm; 50-85 g. Male has buffish-white forehead, crimson-red crown and nape (feathers long, narrow), narrow black hindneck; rest of head and neck white, ear-coverts streaked or mottled greyish, faint buff or pale greyish malar stripe, and large black patch on side of neck which curves up in narrow stripe behind ear-coverts (occasionally almost to nape) and down on to side of upper breast; dull black mantle and inner scapulars to uppertail-coverts, mainly white outer scapulars and inner wing-coverts with some black at base; black flight-feathers with large white spots forming 4-6 broken bars; uppertail black, outer 2 rectrices with white tips and outer webs, latter with 2-3 dark bars; white below, breast and flanks strongly tinged yellow-buff, becoming pinkish on upper belly and lower flanks, darker pink vent and undertail-coverts, long black streaks on sides of breast and flanks usually well defined; medium-length bill rather pointed, lead-grey or

darker, paler base of lower mandible; iris red-brown or red; legs lead-grey, sometimes tinged greenish. Female is like male, some almost identical, but often red of crown paler, becoming browner to golden at rear, pale areas of head more buff. Juvenile duller than adult, especially on head (crown feathers shorter, less narrow), has brownish tips in pale areas of body, some brown in white wing patch, is greyer below, pink area paler and smaller, streaking more diffuse and usually hint of thin bars on flanks, eyes often grey-brown, male with grey-mottled red crown becoming blackish with red tips on nape, female with smaller area of duller red,

hindcrown mostly black. Race *caucasicus* is brighter below than nominate, belly more golden-yellow, pink of ventral region less extensive but redder, breast sides and flanks more heavily streaked, outer rectrices more strongly and symmetrically barred; *anatoliae* is very similar to previous but marginally smaller, perhaps with heavier markings below, paler vent; *sanctijohannis* has much whiter head and underparts, yellow restricted to band across lower belly, deeper pink-red vent and undertail-coverts. **Voice.** Most frequent vocalization is rattle call "kig-gag-gag-gag", most commonly with 3 or 4 elements; long-drawn, loud nasal "gwaag" series territorially in spring, unmistakable. Instrumental signals include loud tapping at nest-hole, rarely drumming.

**Habitat.** Restricted to mature deciduous forest; prefers mixed oak (*Quercus*) and hornbeam (*Carpinus*) in primeval forest. Original habitat in C Europe probably floodplain-forest and hillsides covered with mature oak or beech (*Fagus sylvatica*), but nowadays depends on presence of oaks in large parts of range; old open orchards bordering deciduous woodland also used, but of dwindling importance. Occupies beech, mixed oak-beech and oak forest in S, and beech forest in NE Anatolia and Caucasus. Generally below 600 m, locally to 700 m or more (900 m); 300-1700 m in Italy; reaches 2300 m in SW Iran.

**Food and Feeding.** Bark-dwelling arthropods, caterpillars, dipterans, aphids, also plant material; no wood-boring larvae. Small beetles and ants predominate in adult food; nestlings fed with caterpillars, bugs, lice, beetles, hymenopterans and dipterans, as well as arachnids. Plant material taken mainly in winter, but fruits (cherries, plums, grapes) sometimes eaten during breeding season and even fed to nestlings; in winter, nuts (acorns, hazel nuts, walnuts, beech, rarely seeds of conifers) of some importance. Forages mostly singly; may join mixed-species flocks with tits (Paridae) and other woodpecker species. Explores most levels of trees; rarely descends to the ground. Seasonal differences in parts of tree preferred for foraging: in winter larger branches of lower crown, as well as trunks, are searched, trunks becoming most important in late winter and early spring, whereas in late spring use of the crown increases. About a third of foraging, particularly by males, is on dead wood. Probing and gleaning are most frequent techniques; usually does not hammer persistently; flycatches to some extent. Use of anvils not very frequent and not well developed. Ringing of trees and sap-sucking is common in early spring. Slight foraging differences between sexes outside breeding season probably due to dominance of males.

**Breeding.** Mid-Apr to beginning of May. Conspicuous crest-raising display, near hole also flutter-aerial display. Nest excavated by both sexes, taking 8-20 days, at up to 20 m, mostly 5-10 m, in trunk or in larger branch of deciduous tree, mainly in dead or decaying wood; cavity depth c. 35 cm; old hole frequently reused. Clutch 4-8 eggs, usually 5-6; incubation by both sexes, period 11-14 days; both also contribute to nest sanitation and feed chicks, nestling period 20-26 days; fledglings accompanied by parents for 8-11 days. First breeding at 1 year.

**Movements.** Resident; short-distance dispersal may lead individuals outside breeding range.

**Status and Conservation.** Not globally threatened. Fairly common to common, but often rather local. European population estimated at 62,000-78,440 pairs, with additional 1000-10,000 in European Russia and similar number in Turkey; main strongholds in Germany (9000-13,000), Poland (c. 11,000), Croatia (9000) and Belarus (7000). Densities in C Europe 0.3-2.4 pairs/10 ha, but 1 pair/10 ha in most oak woodlands; average 0.6 pairs/10 ha in area of 122 km<sup>2</sup> (with 7920 ha of woodland) in SW Germany. Has increased and expanded in NC Europe: first 20th-century record in Estonia in 1990; returned as breeder to Netherlands in 1997 (10 pairs), having not bred there since 1962. On other hand, strong decline and local extinctions in many parts of range; last bred S Sweden in 1980. Exact figures, however, rarely available. Most sensitive to habitat deterioration through forestry practices (loss of old-age hardwood stands) and forest fragmentation. Climatic changes and adverse weather also influence populations locally.

## 104. White-backed Woodpecker

*Dendrocopos leucotos*

**French:** Pic à dos blanc      **German:** Weißrückenspecht      **Spanish:** Pico Dorsiblanco  
**Other common names:** Owston's Woodpecker (*owstoni*)

**Taxonomy.** *Picus leucotos* Bechstein, 1803, Silesia, south Poland.

Genus sometimes merged into *Picoides*. No very close relatives within genus; has hybridized rarely with *D. major*, and probably closest to that superspecies; similarity to *D. medius* may suggest relatedness, but this not borne out by available genetic data. Subspecific differentiation largely a

result of vast range that includes many isolated and island populations, some of which are highly distinctive and possibly merit status of full species; SW race *lifordii* possibly also a distinct species, separated by altitude and ecology from parapatric nominate race. Other described races are *uralensis* (W Siberia), *vozniesenskii* (E Siberia and Kamchatka), *saghalinensis* (Sakhalin), *ussuriensis* (Ussuriland and NE China), *sinicus* (Korea) and *quelpartensis* (Quelpart I), all considered inadequately differentiated or representing intergrades. Ten subspecies recognized.

#### Subspecies and Distribution.

- D. l. leucotos* (Bechstein, 1803) - W Norway, Sweden, Finland and Poland S in Europe to E Switzerland, Austria, N Serbia and Carpathian Mts, and E through S taiga to Kamchatka, Sakhalin, NE China and Korea.  
*D. l. lifordii* (Sharpe & Dresser, 1871) - Pyrenees, C Italy, the Balkans and Peloponnese, Turkey (N Anatolia, Taurus Mts), Caucasus and Transcaucasia.  
*D. l. subcirris* (Stejneger, 1886) - Hokkaido (N Japan).  
*D. l. stejnegeri* (Kuroda, 1921) - N Honshu (NC Japan).  
*D. l. namiyei* (Stejneger, 1886) - S Honshu, Shikoku, Kyushu and Quelpart I (Cheju-do).  
*D. l. takahashii* (Kuroda & Mori, 1920) - Dagelet I (Ullung do), off E Korea.  
*D. l. owstoni* (Ogawa, 1905) - Amami-oshima (N Ryukyu Is).  
*D. l. tangi* Cheng Tschin, 1956 - C China (Sichuan).  
*D. l. fohkiensis* (Buturlin, 1908) - SE China (Fujian).  
*D. l. insularis* (Gould, 1863) - Taiwan.

**Descriptive notes.** 23-28 cm; 99-112 g (Europe, Russia), 92-158 g (China), 115 g (*lifordii*). Male has white forehead and lores tinged grey or buff, red forecrown to upper nape (often some black feather bases visible), black lower nape and band down central hindneck; white face and rear part of side of neck, often pale buffish area behind eye, and with black malar stripe meeting fairly large black patch on side of neck that extends up behind ear-coverts (not reaching nape) and down on to side of breast; white chin and throat; slightly glossy black mantle and most of scapulars, white back and rump extending partly on to lower scapulars

(some dark feather bases usually visible), black uppertail-coverts; black wings, greater coverts tipped white, flight-feathers including tertials with broad white spots forming prominent bars; uppertail black centrally, third pair tipped white, outers white with 3-4 narrow black bars; white to pale creamy below, black streaks from breast to flanks and belly sides, reddish-pink belly to undertail-coverts (and often lower flanks); long bill chisel-tipped, dark slate-grey; iris red-brown or red; legs grey. Female has entire top of head black. Juvenile duller and browner than adult, pale areas tinged grey or buff, markings below more diffuse, red area on vent smaller and paler, both sexes with red or orange-red on crown, reduced on female, usually mixed with black. Races vary mainly in coloration and markings, also in size: *lifordii* is darker than nominate, rump mostly black, black barred black, red below more extensive; *subcirris* differs little from nominate, has buff tinge to face, more black on neck and breast, ventral region paler, pinker; *stejnegeri* is slightly smaller and darker than previous, rump partly barred, darker and more streaked below, pink on ventral area more extensive; *namiyei* as last but buffer face, fully barred back and rump, little white in wing, side of breast broadly black with heavy streaking below, darker pink ventral region; *takahashii* resembles previous, but wing and bill shorter, more white above, face and underparts much paler; *owstoni* is distinctive, largest and darkest of all, black above, very little white in wings and tail, face and throat pale buff, very dark below, breast mainly black with broad streaks below, dark pink-red lower breast to undertail-coverts; *fohkiensis* is nearly as dark as previous, but smaller, with some white on back, paler below with less black on breast; *tangi* very like last, but bigger, less black below; *insularis* is smallest, rather similar to previous, but more white on back, more extensive pink below. Voice. Soft low "gig"; series of "kyig gyig" notes in alarm; also "gig gig kwerrrr", and "gaee" calls interspersed with drumming. Drumrolls long, moderately fast, slightly accelerating.

**Habitat.** Old-growth and overmature but relatively open deciduous and mixed forest with high proportion of dead trees and fallen timber, favouring stands older than 80 years; often on steep slopes or near water. In primeval E European forest, prefers swampy woods with ash (*Fraxinus*) and alder (*Alnus*) and stands of oak (*Quercus*) and hornbeam (*Carpinus*); occasionally in coniferous stands. In light, sunny mixed forest (beech-oak, beech-fir, maple-spruce and similar) little affected by management in C Europe and Pyrenees. Closely associated with mature montane forest dominated by *Abies cephalonica* on the Peloponnese. Deciduous forest, particularly birch (*Betula*), mixed light coniferous forest, and willows (*Salix*) along floodplains in Siberia. Japanese populations depend to great extent on natural beech forest. Requires large continuous areas of suitable habitat; enters burned areas and those devastated by insect plagues. Lowlands in E Europe and N Asia; at 400-1850 m in Pyrenees and Alps; between 860 m and 1740 m on the Peloponnese; from sea-level to montane forest in Japan.

**Food and Feeding.** Specializes on large wood-boring insect larvae, mainly cerambycid (*Aromia*, *Necydalis*, *Rhagium*, *Superda*, *Strangalia*) and buprestid coleopterans, and Lepidoptera (*Cossus*, *Lamelloccossus*); also takes other insects, including adult beetles, ants and their larvae. Some plant material consumed, including wild cherries and prunes, berries (*Rhus*); acorns and hazel nuts taken in summer. Singly, occasionally in pairs. Most foraging is on dead trees, least so in late spring and summer. Both sexes prefer the trunk as a foraging site. Techniques include stripping off bark, hammering holes through bark, and hammering on already exposed wood. Males hammer more strongly and more persistently than females, more often visit live and taller trees, and forage on larger branches. Foraging techniques change seasonally, with gleaming most common in post-breeding season, then comprising about a quarter of all techniques used; occasionally hunts aerial prey.

**Breeding.** Laying from late Apr, but significant courtship from Feb; season extends to May or Jun, is c. 2 weeks earlier than other woodpeckers in same habitat. Display with bill-pointing, relatively slow lateral swinging, and flutter-aerial display. Both sexes work for 2-4 weeks on excavating nest, at up to 20 m in soft wood of a dead or decaying trunk, stump or branch, or in utility pole; hole entrance c. 5.5-7 cm high, 4.7-6.4 cm wide, cavity depth 25-37 cm. Clutch 3-5 eggs; both parents incubate eggs and feed chicks, female's share often less; incubation period 14-16 days, occasionally only 12; fledging period 27-28 days. Breeding success 2.4 fledglings per nest in a 10-year study in Norway.

**Movements.** Generally resident; some local movements. A few individuals seem to be carried along with eruptive movements of *D. major*; sometimes relatively large numbers undertake longer migrations, e.g. at least 100 juveniles together with considerably larger numbers of *Picoides tridactylus* seen along coasts of Finland in autumn 1993. A degree of dismigration occurs among N Asian populations after breeding.

**Status and Conservation.** Not globally threatened. Seems to be at best uncommon in most of its range, and in many parts rare or extremely rare, but may be commonest woodpecker in parts of

Siberia. Population in Europe and W Russia estimated at c. 67,000 pairs, mostly in E parts, including 17,000 in Romania and 8000 in Belarus. Maximum densities in optimal habitat 1 pair/km<sup>2</sup> in N & C Europe, 2 pairs/km<sup>2</sup> in Italy, but elsewhere usually much lower. Pairs require large home range, e.g. 50-100 ha in Sweden, 100 ha in Poland, 75-150 ha in Norway; 0.3-0.77 pairs/100 ha in SW France (Pyrenees). Numbers have decreased in many parts of Europe; massive decline in Fennoscandia, from 1000 pairs in early 1950's to only 30-40 pairs in late 1990's; only 3 isolated populations remain in Sweden. More stable in SE & E Europe; has extended range in Slovenia, and first bred in Switzerland in 1999. Often overlooked because of its secretive habits and very large territories. Since mid-20th century has become endangered wherever forest management is intense, leading to reduction of dead stems or introduction of conifers; reduction in population size is accompanied by loss of genetic diversity. Race *owstoni*, confined to old mature evergreen broadleaved forest in hills of Amami-oshima, is rare; *insularis* fairly common on Taiwan; status of other island populations uncertain. Everywhere, this species' survival is dependent on preservation of reasonably large areas of unmanaged deciduous forest.

## 105. Great Spotted Woodpecker

### *Dendrocopos major*

French: Pic épicé

German: Buntspecht

Spanish: Pico Picapinos

Other common names: Greater Pied Woodpecker

**Taxonomy.** *Picus major* Linnaeus, 1758, Sweden.

Genus sometimes merged into *Picoides*. Forms a superspecies with *D. syriacus*, *D. leucopertus*, *D. assimilis* and *D. himalayensis*. Hybridizes rarely with first two, and named race *tianshanicus* from C Tien Shan considered to refer to offspring of mixed pairs of present species and *D. leucopertus*; has also interbred with more distantly related *D. leucotos*. Variation over vast range is largely clinal, with races intergrading extensively and many intermediate populations. Many additional named races thus not certainly identifiable, and considered unacceptable: *anglicus* (Britain), *italiae* (Pyrenees E to Switzerland and Italy), *parroti* (Corsica), *lynesi* (Atlas Mts in Morocco), *candidus* (S Russia, Romania, Bulgaria), *paphlagoniae* (N Turkey), *tenirostris* (Crimea, Caucasus, Transcaucasia), *tscherskii* (Ussuriland and Sakhalin), *hondoensis* (N & C Honshu and smaller islands), *beckii* (Gansu, in W China), *mandarinus* (S & SE China) and *hainanus* (Hainan I). Fourteen subspecies recognized.

#### Subspecies and Distribution.

- D. m. major* (Linnaeus, 1758) - Scandinavia and W Siberia E to Urals and S to N Poland and N Ukraine.  
*D. m. brevirostris* (Reichenbach, 1854) - from W Siberia E to lower R Amur, Manchuria and Sea of Okhotsk, and S to C Tien Shan and Mongolia.  
*D. m. kamtschaticus* (Dybowski, 1883) - Kamchatka and N Okhotsk coast.  
*D. m. pinetorum* (C. L. Brehm, 1831) - Britain, France and C Europe E to R Volga and S to Italy, Balkans, Turkey, S Ukraine and Caucasus.  
*D. m. hispanus* (Schlüter, 1908) - Iberia.  
*D. m. harterti* Arrigoni, 1902 - Sardinia and Corsica.  
*D. m. canariensis* (König, 1889) - Tenerife, in Canary Is.  
*D. m. thanneri* le Roi, 1911 - Gran Canaria.  
*D. m. mauritanus* (C. L. Brehm, 1855) - Morocco.  
*D. m. numidus* (Malherbe, 1843) - N Algeria and Tunisia.  
*D. m. poelzami* (Bogdanov, 1879) - S Caspian region and Transcaspius.  
*D. m. japonicus* (Seeböhm, 1883) - C & E Manchuria to Sakhalin and Kuril Is, and S to Korea and Japan (Hokkaido, Honshu, Tsushima).  
*D. m. cabanisi* (Malherbe, 1854) - S Manchuria S to E Myanmar, N Laos, N Vietnam (NW Tonkin), SE China and Hainan.  
*D. m. stresemanni* (Rensch, 1924) - C China (E Qinghai, Gansu, Shaanxi, Sichuan) S to SE Tibet, NE India, W & N Myanmar and Yunnan.

**Descriptive notes.** 20-24 cm; 70-98 g (*major*), 68-93 g (*pinetorum*), 66-98 g (*cabanisi*). Male has black nasal tufts, white to buffish forehead, blue-glossed black crown, bright crimson-red nape, black hindneck with large white patch on each side; white to creamy lores and side of head bordered below by black stripe from nape to base of lower mandible, black broadening in centre and extending to side of breast; bluish-black upperparts, often greyish feather bases visible on rump, white outer scapulars; innermost greater and median wing-coverts white, joining with outer scapulars to form large white patch; black or brownish-black flight-feathers with up to 6 white spots forming prominent bars, some white in primary coverts; uppertail black, off-white bars at tips of rectrices increasing in size from second-innerness outwards, two outermost pairs mostly white with 2 or 3 black bars; generally white, pale greyish-white or buff-white below, bright scarlet vent and undertail-coverts; strong bill short to moderately long, chisel-tipped, blackish-grey, lead-grey or slate-grey, paler base of lower mandible; iris deep red or reddish-brown; legs slate-grey, tinged olive or brown. Distinguished from *D. syriacus* by black behind ear-coverts, more white in outer tail, redder vent, smaller red nape patch; from *D. leucopertus* by less white in wing, less extensive red on vent. Female lacks red on nape. Juvenile less glossy, more brown-tinged

above, bases of white scapulars often with black barring, malar less sharply defined, post-auricular bar narrower and sometimes not extending to nape, dirtier underparts often with dusky streaks, flanks sometimes barred, ventral area pink or occasionally even buff or whitish, rarely some pinkish colour on breast, eyes browner, male with red crown narrowly edged black, red usually less extensive on female. Races differ both in size and in plumage, as well as in length and shape of bill, generally N populations bigger, with shorter, heavier bill, whiter below: *brevisrostris* is very like nominate but slightly bigger, plumage very fluffy, perhaps whiter below, vent deeper red; *kamshaticus* similar but even whiter, white wing patch bigger, outer tail all white; *pinetorum* is smaller, has longer, narrower bill, light buffish underparts; *hispansus* resembles previous but darker; *harteri* like last but bigger, dark grey-brown below, darker red vent; *canariensis* as previous but not quite so dark, has contrasting whitish flanks, more orangey vent; *thanneri* is paler than last, with white from flanks up to breast; *mauritanus* is rather pale below, often with red in breast centre, size and darkness increasing clinally with altitude; *numidus* distinctive, larger than previous, has black breastband with red feather tips, red of vent often extending to belly; *poelzami* is rather small, with proportionately long bill, very brown below; *japonicus* is blacker above, has less white on scapulars, more white on flight-feathers; *cabanisi* is even blacker above, has buff-brown head and underparts, darkest in S, paler pink vent, often some red on breast; *stresmanni* resembles previous but even darker below, again darkest in S. Voice. Single sharp "kix", in alarm sometimes in rapid series; wooden "krarraarr" of varying length and introduced by "kix"; series of "gwig" notes in courtship season, especially during flutter-aerial display. Both sexes drum, male much more frequently, from winter until fledging period, rolls rather short, slightly accelerating.

**Habitat.** All kinds of woodland and forest, from pure broadleaved forest to unmixed stands of conifers; also common in copses, tree avenues, parks, gardens. Inhabits olive and poplar (*Populus*) plantations and up to cedar (*Cedrus*), pine (*Pinus*), pine-oak and cork oak (*Quercus suber*) woods in N Africa; found in alder (*Alnus*) and rhododendron in N Myanmar; common in deciduous, mixed or coniferous woods, and parks in Japan. Occurs from sea-level to the timber-line in Europe, where breeding recorded at over 2000 m; in N Africa, to 1000 m in Tunisia, 2200 m in Morocco; to 2500 m in C Asian mountains; *cabanisi* occupies forest above 1800 m in SE Asia; at up to 2300 m in N Myanmar and Japan.

**Food and Feeding.** Very varied diet, with clear seasonal changes in more seasonal habitats. Animal food consists mainly of larvae of wood-boring beetles (Cerambycidae, Scolytidae, Buprestidae), Lepidoptera (Cossidae, Sesiidae) and Hymenoptera (Siricidae); adult beetles (Curculionidae, Chrysomelidae, Carabidae), hymenopterans, hemipterans, homopterans (e.g. Aphidina, Coccoidea), spiders and many other arthropods also consumed. Ants can form substantial part of diet, and include genera *Lasius*, *Formica*, also *Camponotus* and *Dolichoderus*. Also takes crustaceans and mussels, carrion (small mammals), and obtains suet and other food, including household scraps, at feeders. Notorious for taking eggs and young of other hole-nesting birds; also raids open nests and nest pouches. Plant material rich in fat, mostly in form of coniferous seeds and various nuts (e.g. hazel, walnut, beech, hornbeam), and acorns (particularly in Caucasus), become more important as winter food towards N of range; seeds usually contribute c. 30% but often up to 80% of energy intake in winter. Other vegetable matter includes buds and, of major importance locally and seasonally, tree sap, and possibly nectar; wide array of berries and fruit also regularly eaten, and even fed to nestlings. Forages singly, also in pairs with members keeping in loose contact. Makes use of all strata, mainly tree crowns in winter, may resort more frequently to lower trunk in summer; in canopy visits branches and small twigs. Climbs quickly, mostly straight up, but often backwards and downwards; in crown prefers to climb rather than to use wings. Clings to twigs and leaf clusters in manner of tits (Paridae); occasionally hovers briefly, and sallies for aerial prey. Pecking and hammering are commonest techniques, especially outside breeding season; pries, tears and pecks off pieces of bark; gleaning and probing more important at times of high food availability. Generally rather opportunistic, and seasonal and local differences marked; sexual differences minimal. Drilling of sap holes and sap-sucking very common. Uses anvils to work on unwieldy arthropod prey, fruits and, most importantly of all, pine, spruce (*Picea*) or larch (*Larix*) cones, and nuts; single main anvil, with 1000s of processed cones, and several ancillary anvils maintained.

**Breeding.** Laying from mid-Apr to Jun, later in far N and at higher altitude, but courtship commences in Dec. Monogamous, but polyandry also recorded in Japan. Flutter-aerial display mostly by male flying away from partner, shallow wingbeats, fully spread tail turned upwards, with call series; on landing, may demonstrate prospective nest-hole. Usually a new hole excavated annually, by both sexes, mostly by male, at 0.3-26 m, usually below 8 m (but in primeval forest in Poland average 12 m), in dead or live tree of wide variety of species, occasionally in utility pole; hole entrance 5-6 cm across, cavity depth 25-35 cm; occasionally in nestbox, rarely old hole reused. Clutch 4-8 eggs, normally 5-7; incubation by both sexes, period 10-12 days; both also feed chicks and attend to nest sanitation, fledging period 20-23 days; fledged brood divided between parents, fed by them for 10 days, remain near nest for further 5-10 days. First breeding at 1 year. Recorded longevity in wild 9 years.

**Movements.** Largely resident and dispersive; N populations also subject to eruptive migration. Juvenile dispersal often over 100 km, and up to c. 600 km. In N Europe, periodic eruptive movements triggered by poor crop of pine or spruce seeds, begin in late Jul; small groups and loose flocks migrate S & W, and occasionally large numbers involved, e.g. 2240 through Pape, in Latvia, during Aug-Oct 1999, and sizeable flocks recorded in N Britain in autumn 2001; individuals may stray more than 3000 km, some reaching oceanic islands. Similar movements in Far East, but less well studied; stragglers found even on remote islands. Also, populations in mountain areas descend to valleys in winter.

**Status and Conservation.** Not globally threatened. In many parts of range by far the commonest woodpecker; less common locally, and rare in SE Asia. In Europe estimated population c. 3,300,000-4,480,000 pairs, with further 1,000,000-10,000,000 in European part of Russia; largest numbers in Germany (500,000-900,000 pairs), Belarus (c. 600,000) and France (over 300,000). Densities vary from 0.1 pairs/10 ha to 6-6 pairs/10 ha, highest in mature alluvial forest. Increase in extent of forested area, with greater proportion of dead wood, has resulted in stable or slightly increasing numbers in many regions in Europe. On other hand, harsh winters can cause significant mortality, and fragmentation of habitat can pose problems locally: Canary Is races *canariensis* and *thanneri* are currently probably the most vulnerable, especially the former, which may be at some risk because of human exploitation of Canarian pine forest. Nevertheless, species is generally highly adaptable in much of its range, capable of existing in very close proximity to man, and able to colonize wide variety of wooded habitats.

## 106. Syrian Woodpecker

### *Dendrocopos syriacus*

French: Pic syriaque

German: Blutspecht

Spanish: Pico Sirio

**Taxonomy.** *Picus syriacus* Ehrenberg, 1833, Mount Lebanon.

Genus sometimes merged into *Picoides*. Forms a superspecies with *D. major*, *D. leucopterus*, *D. assimilis* and *D. himalayensis*; has hybridized rarely with first and third of those. Some geographical variation, e.g. smaller birds in N Iran and Transcaucasia named as race *transcaucasicus*, often with more white in outer tail, while latter population and also those from Asia Minor tend to be darker below, but overlap in characters exists between these and other populations; similarly, *balcanicus* (E Balkans) with dark flank marks and supposedly larger *milleri* (S Iran) matched by individuals from elsewhere in range; subdivision into geographical races seems unwarranted. Monotypic.

**Distribution.** Austria, Czech Republic, Poland and S Belarus E to W & S Ukraine and SW Russia, and S to Balkans, Turkey, Levant countries, extreme NE Egypt (NE Sinai), N Iraq, Transcaucasia, and to N, W & S Iran.

**Descriptive notes.** 23 cm; 55-63 g (Iran), 70-82 g (C Europe). Male has buffy nasal tufts and lower forehead, white to creamy upper forehead, black crown (rarely, a few scattered red feathers), red central hindcrown and nape, black hindneck; rest of head white, including thin line above eye, with black malar stripe expanding a little upwards on side of neck and continuing down to side of upper breast; dull black upperparts, white outer scapulars and innermost greater coverts, also some white median coverts, remaining wing-coverts black but outer primary coverts mostly white; black flight-feathers with large white spots forming

3 wingbars; uppertail black, outer feathers with a few white spots or white tip, next-inner rectrix sometimes with 1 white spot or bar; white to pale creamy below, becoming pinkish-red on lower belly to undertail-coverts, often faint dusky streaks or bars on lower flanks; rather long bill almost straight, chisel-tipped, dark grey to slaty-blue, paler base of lower mandible; iris red-brown, sometimes deep red; legs slate-grey with blue, brown or olive tinge. Distinguished from *D. major* by more white on head, including more extensively pale forehead, less white in tail, larger red nape patch, duller black upperparts, pinker (less red) vent, pale nasal tufts; from *D. assimilis* by black crown, stronger malar and stripe on side of breast, less white in tail. Female resembles male, but lacks red on nape. Juvenile slightly duller than adult, but often some pinkish feathers across upper breast (rarely, complete band), flanks usually with obvious streaks and bars, sometimes reaching breast side, both sexes with black-bordered red crown, black nape. Voice. Commonest call a single "kweg" (better rendered as "piüg", or "puc" pronounced as in French *duc*), sometimes in rapid series when alarmed at nest; also loud "kweg-kweg kririrrrrrr"; loud series of distinct "kweek" notes characteristic during courtship. Drumming, mainly by male, in accelerating rolls up to twice as long as those of *D. major*.

**Habitat.** Open country with wooded areas. Often in plantations of all kinds, including olive, pecan (*Carya*) and avocado in S, and vineyards in C Europe, where also in roadside trees, groups of trees, mainly near habitations, also forest edge, parks and gardens. Inhabits oak (*Quercus*) woodland and light montane forest in SE; also breeds in coniferous forest at lower levels in Turkey. Lowlands to 700 m in C Europe; to 1000 m in Bulgaria and C Anatolia; reaches 2700 m in S Iran.

**Food and Feeding.** Animal food and a relatively large amount of plant material. Beetles and their larvae, ants, lepidopterous larvae (even hairy ones) and pupae; spiders; also various aerial insects. Nuts and seeds eaten both in summer and in winter, include almonds, walnuts, pecans, hazel nuts, apricot stones, acorns, pine seeds, sunflower seeds, pistachios and similar; ripe fruits (e.g. apricots and prunes) taken to get at the seeds. Takes the flesh of cherries, mulberries, raspberries and other fruits, which may also be fed to nestlings. Sap sometimes taken. Forages singly and in pairs. Uses all levels, from ground to canopy, but almost half of all foraging takes place in lower strata. Hops on the ground, and moves swiftly during arboreal feeding. Marked seasonal changes, from foraging more in crown in winter to opportunistic habitat use during nesting season. Especially in summer, gleaning and probing most common foraging activities, and commonly takes prey on the wing. Anvils used frequently to process large insects (beetles), fruits and nuts. Covers relatively large distances between feeding sites, and between them and the nest.

**Breeding.** Lays from mid-Apr to May, rarely to Jun. Lateral swinging displays and aerial chasing. Nest-hole excavated by both sexes, mostly by male, at 1-6 m in trunk or large branch of tree, with wide variety of species used, less often in utility pole or similar structure; hole diameter averages 3.5 cm, cavity depth 20 cm; old nest sometimes reused. Clutch 3-7 eggs, usually 4 (Israel) or 5 (Hungary); incubation by both sexes, period 9-11 days; both also feed chicks and share nest sanitation, nestling period c. 20-24 days; juveniles accompanied by parents for 2 weeks.

**Movements.** Resident and dispersive. Long distances covered during dispersal, but no seasonal movements have been documented.

**Status and Conservation.** Not globally threatened. Common in most parts of range. European population estimated at c. 170,000 pairs, including 80,000 or more in Romania and at least 30,000 in Bulgaria; Turkish population 10,000-100,000 pairs, probably nearer lower end of that range. Densities much lower than those of *D. major*; highest in orchards and vineyards, where 0.5-1 pair/100 ha. Considerable range extension since late 19th century; formerly restricted to E Mediterranean, it spread via Balkans to C Europe, also E to Ukraine; had colonized almost whole of Hungary by late 1950s after first recorded there in 1937; rather rapid expansion to N & W in Poland since c. 1980. Range expansion probably fostered by agricultural development and other human activities.

Some local declines in SE Europe (Greece, Albania) since c. 1985. Causes some damage in commercial plantations, especially of almond, also pecks holes in irrigation pipes in parts of Middle East; was formerly persecuted locally as a pest, and sometimes large numbers shot, but generally tolerated in more recent times.

**Bibliography.** Adamian & Klem (1999), Barnea (1985), Bauer, K.M. ## 107. White-winged Woodpecker

### *Dendrocopos leucopterus*

**French:** Pic à ailes blanches **German:** Weißflügelspecht **Spanish:** Pico Aliblanco  
**Other common names:** White-winged Pied/White-winged Spotted Woodpecker

**Taxonomy.** *Picus* (*Dendrocopos*) [*sic*] *leucopterus* Salvadori, 1870, Yarkand, Kashgaria, in extreme west China.

Genus sometimes merged into *Picoides*. Forms a superspecies with *D. major*, *D. syriacus*, *D. assimilis* and *D. himalayensis*; has hybridized very occasionally with first of those. Birds of the Turkestan uplands, described as race *leptorhynchus*, tend to be less white, but difference minor and not constant, and racial separation regarded as unwarranted; named races *albipennis* (SE Turkmenia), *jaxartensis* (lower R Syr Darya) and *korejevi* (SW Alatau Mts) likewise insufficiently differentiated. Monotypic. **Distribution.** W shore of Aral Sea E to S Kazakhstan, N Kyrgyzstan (N to S tip of L Balkhash) and W China (N Xinjiang to Karamay and Lop Nur), and S to SW Turkmenia (possibly also extreme NE Iran) and NE Afghanistan in W and Chinese Turkistan S to edge of Kunlun Shan in E.

**Descriptive notes.** 22-23 cm; 67 g. Male has white forehead, black crown, red nape, black hindneck; thin white line above eye, white cheeks and ear-coverts (often stained); black malar stripe curving up behind ear-coverts to upper nape, broadening on side of neck, extending down to breast and back to join side of mantle, isolating large white patch on rear part of side of neck; black upperparts, wing with large white area on scapulars and inner wing-coverts, very broad white bars on primaries and secondaries, white edges of outer webs of tertials, white marginal coverts; black upperpart, broad white bars towards tips of outer 2 or 3

feather pairs; white below, sometimes with faint grey or buff tinge or staining, vent and undertail-coverts red to pinkish-red, in fresh plumage pink feather tips extending centrally up to lower breast; medium-long bill straight, slightly chisel-tipped, greyish-black, paler base of lower mandible; iris deep red, red-brown or brown; legs dull blackish or dark grey. Distinguished from all congeners by much more extensive white in wings. Female lacks red on nape. Juvenile duller than adult, more brown-black above, buffish below, often more white in wings and tail but occasionally scapulars finely barred black, ventral area pink rather than red, sometimes black streaks on side of breast, male with red crown mixed with black and white feathers, black nape, female with usually variable amount of red in forecrown. **Voice.** Common call "kewk" or "kig"; also rattling calls. **Drums.**

**Habitat.** Riparian woodland with poplars (*Populus*) and other softwoods, willows (*Salix*), saxaul (*Haloxylon ammodendron*) scrub in deserts, frequently orchards and gardens. Also found in broadleaved montane forest, often containing hazel (*Corylus*) and fruit trees or mixed with fir (*Abies*) or juniper (*Juniperus*), and in juniper stands. Generally at low elevations, locally to 1050 m; above 1800 m, to 2500 m, on N slopes of Kunlun Shan.

**Food and Feeding.** No reliable information.

**Breeding.** Egg-laying from late Mar to Apr. Nest-hole at 1-5 m in softwood tree (e.g. poplar, willow), also recorded in slope of sandhill. Clutch 4-6 eggs, occasionally 7; no information on incubation and fledging periods.

**Movements.** Some nomadic movements outside breeding season, but essentially non-migratory.

**Status and Conservation.** Not globally threatened. Previously considered Near-threatened. Appears to be common within its range. Little-known species; further study required, especially of its ecology.

**Bibliography.** Collar *et al.* (1994), Dementiev *et al.* (1966), Étchécopar & Hüe (1978), Friedmann (1997), Hollom *et al.* (1988), Hüe & Étchécopar (1970), Inskipp *et al.* (1996), Knystautas (1993), MacKinnon & Phillips (2000), Porter, Christensen & Schierner-Hansen (1996), Wheatley (1996), Winkler & Short (1978), Zhao Zhengjie (1995).

## 108. Sind Woodpecker

### *Dendrocopos assimilis*

**French:** Pic du Sind **German:** Tamariskenspecht **Spanish:** Pico del Sind  
**Other common names:** Sind Pied Woodpecker

**Taxonomy.** *Picus assimilis* Blyth, 1849, Rawalpindi, Punjab.

Genus sometimes merged into *Picoides*. Forms a superspecies with *D. major*, *D. syriacus*, *D. leucopterus* and *D. himalayensis*; hybridizes rarely with second of those. Monotypic.

**Distribution.** SE Iran and Pakistan (Baluchistan, Sind and Punjab).

**Descriptive notes.** 20-22 cm; 42-64 g. Male has red crown and nape usually with some black or grey feather bases visible, black hindneck; rest of head and neck white, usually stained buffish on forehead and lores, sometimes dusky area in centre of ear-coverts, with narrow black malar stripe from bill to just behind lower ear-coverts, joined to black stripe that continues back to upper mantle and narrowly forwards to uppermost part at side of breast; blue-glossed black upperparts, large area of white on mostly inner wing-coverts and reaching to outermost scapulars; brownish-black flight-feathers broadly barred white; uppertail black, outer 2 feather pairs with broad white bars (rarely, much reduced or almost absent); white below, occasionally very faint grey or buffy tinge, flanks with minimal black streaking barely visible, pink in centre of lower breast and belly, red undertail-coverts; longish bill almost straight, slate-grey, paler lower mandible; iris red-brown to brown; legs grey to blue-grey. Differs from *D. syriacus* in smaller size, red crown, black stripe from side of neck to mantle, shorter

black stripe on to breast. Female has entire crown and nape black. Juvenile duller than adult, with black areas browner, white areas buff-tinged, undertail-coverts pink rather than red, both sexes with red patch in crown centre, smaller on female. **Voice.** Single "ptik" call; weak "chir-rir-rir-rir-rir", also "wicka, toi-whit toi-whit toi-whit". Both sexes drum.

**Habitat.** Riverine forest, thorn-scrub, and desert wadis with scattered acacias (*Acacia*) and other thorny trees, and euphorbias; also roadside trees and irrigated plantations, e.g. of mulberry (*Morus*); also palm stands and gardens. Inhabits stands of wild olives (*Olea*

*cuspidata*), *Pistacia integerrima* and ash (*Fraxinus excelsior*) in hilly country. Mainly in lowlands, but in Pakistan ascends to 1600 m in Salt Range and perhaps to 2200 m in Baluchistan.

**Food and Feeding.** Ants, especially *Camponotus*, and larvae of wood-boring beetles. Usually forages singly. Explores branches and twigs of *Acacia*, *Pistacia* and other trees, as well as euphorbias and fence posts; often near ground and on fallen trees. Techniques are hammering and probing.

**Breeding.** Season Mar-Apr. Nest-hole excavated by both sexes, sometimes rather low, c. 1-4 m from ground, in trunk or dead branch, often of tamarisk (*Tamarix*). Clutch 3-4 eggs; incubation by both sexes, period 15-16 days; no other information.

**Movements.** Resident. No movements recorded, but 19th-century record from NW India possibly a result of long-distance dispersal.

**Status and Conservation.** Not globally threatened. Widespread and locally common. Rather rare in lower Sind, commoner in upper Sind and Punjab. Appears fairly adaptable, using several man-made habitats, e.g. plantations alongside roads and canals. Present in Khirthar National Park (Pakistan).

**Bibliography.** Ali & Ripley (1983), Barker *et al.* (1999), Christon (1942), Christon & Ticehurst (1943), Grimmett *et al.* (1998), Hollom *et al.* (1988), Hüe & Étchécopar (1970), Inskipp *et al.* (1996), Porter, Christensen & Schierner-Hansen (1996), Ripley (1982), Roberts (1991), Wheatley (1996), Whitehead (1911), Winkler & Short (1978).

## 109. Himalayan Woodpecker

### *Dendrocopos himalayensis*

**French:** Pic de l'Himalaya **German:** Himalajaspecht **Spanish:** Pico del Himalaya  
**Other common names:** Himalayan Pied Woodpecker

**Taxonomy.** *Picus himalayensis* Jardine and Selby, 1835, Mussoorie, near Dehra Dun, northern India. Genus sometimes merged into *Picoides*. Forms a superspecies with *D. major*, *D. syriacus*, *D. leucopterus* and *D. assimilis*. Races intergrade in N India. Two subspecies recognized.

**Subspecies and Distribution.**

*D. h. albescentis* (Stuart Baker, 1926) - NE Afghanistan (Safed Koh) and N Pakistan to Himachal Pradesh.

*D. h. himalayensis* (Jardine & Selby, 1835) - E Himachal Pradesh E to W Nepal.

**Descriptive notes.** 23-25 cm; 57-85 g. Male has pale buff-white forehead, crimson-red crown to upper nape usually with some black or grey feather bases showing (especially forecrown and crown sides), black hindneck; white lores, superciliary area, cheeks and ear-coverts tinged buff; variable black patch behind eye, often isolated and prominent, sometimes meeting crown, frequently absent; complete black malar stripe expanding on side of neck, joining black stripe that continues slightly down on to side of upper breast and up behind ear-coverts (where often broken) to meet side of hindcrown; rear part of side of neck white to light buffish; entire

upperparts black, inner wing-coverts with much white, flight-feathers barred white; uppertail black, outer 2 feathers largely white with black at base and few black bars at tip, adjacent ones with white bars at tip, but amount of white in outer tail variable, sometimes more black barring; pale buff or greyish-brown below, breast often sullied yellowish-brown, yellow on belly, red on lower belly and undertail-coverts, occasionally hint of streaks or bars on lower flanks; moderately long bill almost straight, chisel-tipped, blackish to dark grey, often paler lower mandible; iris red-brown; legs grey to dull green or green-brown. Female has black crown to nape. Juvenile duller than adult, black areas browner, ventral area pink, not red, and not reaching belly, some streaks on upper flanks and bars on lower flanks, both sexes with white spots on forecrown and orange-red patch in crown centre, smaller on female. Race *albescentis* is paler than nominate, with forehead white, underparts pale greyish-white, narrower white tailbars. **Voice.** Single "kit", much like that of *D. major*; also rapid high "chissik-chissik", and fast "tri" series possibly as long-distance call. Short drumrolls.

**Habitat.** Rather dense, dry to wet, extensive coniferous forest, also oak (*Quercus*) and rhododendron mountain forest, locally in smaller patches of mixed pine (*Pinus*) and juniper (*Juniperus*). Between 1970 m and 3200 m, regionally up to tree-line; also down to 1500 m in Pakistan. Generally replaces *D. auriceps* at higher altitudes.

**Food and Feeding.** Insects and their larvae, other arthropods; also plant matter, possibly including sap. Takes wood-boring beetle larvae, weevils (Curculionidae), caterpillars and spiders; acorns (*Quercus dilatata*) and seeds of pines (*Pinus wallichiana*, *P. longifolia*) important food in winter. Forages singly or in pairs; occasionally joins mixed-species flocks of tits (Paridae) and warblers (Sylviidae). Arboreal feeder, rarely descends to ground. Techniques include pecking, probing, hammering, gleaning. Anvils used for processing pine cones.

**Breeding.** Laying in second half Apr and first half May. Aerial pursuits near nest. Nest-hole excavated by both sexes, mostly by male, at 1.5-15 m, mostly below 12 m, in usually deep cut of trunk or large branch of tree, with local preference for deciduous (e.g. *Prunus cornuta*); entrance hole 5 cm in diameter. Clutch 3-5 eggs; both sexes incubate, period c. 2 weeks; both also feed nestlings, fledging period c. 3 weeks.

**Movements.** Largely resident; some local movement to lower hills may occur in winter.

**Status and Conservation.** Not globally threatened. Common in Pakistan; fairly common in India and Nepal; the commonest woodpecker in most of its range. No known threats, and seems unlikely to suffer any significant habitat loss in immediate future.

**Bibliography.** Ali (1979), Ali & Ripley (1983), Bates & Lowther (1952), Fleming & Traylor (1961), Grimmett *et al.* (1998, 2000), Hüe & Étchécopar (1970), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Kazmierczak (2000), Lohrl & Thieleke (1969), Macdonald & Henderson (1977), Martens & Eck (1995), Osmaston (1916), Raja *et al.* (1999), Ripley (1982), Roberts (1991), Shrestha (2000), Whitehead (1911), Winkler & Short (1978).

Genus *PICOIDES* Lacépède, 1799

## 110. Striped Woodpecker

*Picoides lignarius*

French: Pic bûcheron      German: Strichelkopfspecht      Spanish: Pico Bataraz Grande

**Taxonomy.** *Picus Lignarius* Molina, 1782, Chile.

Forms a superspecies with *P. mixtus*; they seem to be genetically close and may be conspecific, but possible overlap of breeding ranges not well documented. Related more distantly to other American congeners. Birds of isolated N population slightly smaller than those of Patagonia, with other morphological, plumage and genetic differences, probably representing a separate taxon, for which the name *puncticeps* is available; further study currently in progress. Monotypic.

**Distribution.** WC & S Bolivia (La Paz, Cochabamba, Santa Cruz southwards) S to N Argentina (Salta); Andean foothills and lowlands in C & S Chile (Bio-Bío to Magallanes) and SW Argentina (Neuquén to Santa Cruz).

**Descriptive notes.** 15-16 cm; 35-39 g. Male has black forehead and crown, crown with variable amount of streaking or spotting, red to orange-red nape or red sometimes restricted to nape side, blackish hindneck; dark brownish-black ear-coverts faintly spotted white; white from supercilium continuing behind ear-coverts to join broad white line from lores; blackish malar stripe mixed with white feathering, heavily white-streaked near bill; whitish chin, throat finely streaked or spotted black; dark brownish-black upperparts narrowly barred (S population) or scalloped (N population) white to pale brownish-white, wing-coverts with large

white spots, flight-feathers barred white; uppertail dark brownish-black, all feathers narrowly barred white or buff-white; white below, often tinged yellow or buff, and heavily and coarsely streaked blackish (streaks much finer in N population), streaks finer on belly, bars on lower flanks and undertail-coverts; longish bill (shorter in N) virtually straight, black, paler base and lower mandible; iris deep brown; legs grey or grey-brown. Distinguished from extremely similar *P. mixtus* by marginally larger size, slightly darker appearance, narrower white bars above, heavier markings below. Female lacks red on nape, usually has no white crown spots. Juvenile duller and browner than adult, more irregularly barred above, with heavier streaks and bars below, male with entire crown red, female with small red crown patch. VOICE. Loud "peek"; also trill as long-distance call, lower and less harsh than that of *P. mixtus*.

**Habitat.** Humid to transitional forest. *Nothofagus* forest, *Podocarpus* forest, *Polylepis* woodland; open forest and edge of dense forest, open stunted forest, and interior of tall wet forest with water-courses in N; dry areas with scattered trees and cacti. Also found in pastures with shade trees, plantations and orchards; enters gardens. Occurs at 1600-4000 m in Bolivia; to 1800 m in Chile and Argentina.

**Food and Feeding.** Diet unrecorded; presumably includes surface-dwelling insects and wood-boring larvae. Forages solitarily; occasionally joins mixed-species feeding flocks. Main techniques are gleaning and probing; also pecks and hammers.

**Breeding.** Probably in Jun-Sept in Bolivia; from Oct in N to Jan in S in Chile and Argentina. Nest-hole excavated in tree or cactus. Clutch 3-5 eggs; no information on incubation and fledging periods.

**Movements.** Resident; some altitudinal movements. Populations breeding farthest S said to migrate N as far as WC Argentina (La Rioja, Cordoba) after breeding; recent research suggests, however, that this assertion probably based on misidentified specimens and confusion of scientific names.

**Status and Conservation.** Not globally threatened. No information on numbers; probably fairly common. Occurs in Cerro La Campana, Nahuelbuta and Vicente Pérez Rosales National Parks (Chile). A poorly known species; requires study.

**Bibliography.** Araya & Chester (1993), Canevari *et al.* (1991), Chebez *et al.* (1999), Cofré (1999), Ejlsdå & Krabbe (1990), Flores & Capriles (1998), Grigera *et al.* (1996), Herzog *et al.* (1997), Johnson (1967), Mazar Barnett (2001a, 2001b), Mazar Barnett & Pearman (2001), Mazar Barnett *et al.* (1998), Narosky & Yzurieta (1993), de la Peña (1994), Remsen & Traylor (1989), Schmitt *et al.* (1997), Short (1970c, 1985b), Stotz *et al.* (1996), Vuilleumier (1985), Winkler & Short (1978).

## 111. Chequered Woodpecker

*Picoides mixtus*

French: Pic varié      German: Streifenschwanzspecht      Spanish: Pico Bataraz Chico  
Other common names: Checked Woodpecker

**Taxonomy.** *Picus mixtus* Boddaert, 1783, Buenos Aires, Argentina.

Forms a superspecies with *P. lignarius*; they seem to be genetically close and may be conspecific, but possible overlap of breeding ranges not well documented. Races intergrade, and *malleator* and *berlepschi* may be more appropriately lumped into nominate. Four subspecies tentatively recognized.

**Subspecies and Distribution.**

*P. m. cancellatus* (Wagler, 1829) - extreme E Bolivia (Huanchaca Mts) to E Brazil (W Piauí S to S Mato Grosso, W Minas Gerais and Rio Grande do Sul), NE Paraguay and W Uruguay.

*P. m. malleator* (Wetmore, 1922) - Chaco region of SE Bolivia, Paraguay and N Argentina.

*P. m. berlepschi* (Hellmayr, 1915) - C & E Argentina from San Luis and Córdoba S to Neuquén, Rio Negro and S Buenos Aires.

*P. m. mixtus* (Boddaert, 1783) - R Paraná and Buenos Aires (except S).

**Descriptive notes.** 14 cm; 29-8-37 g. Male has blackish-brown forehead and crown faintly streaked white or buffish-white, occasionally some crown feathers tipped red, nape red or orange-red but this

colour often restricted to nape sides, blackish-brown hindneck; dark brown ear-coverts; white from supercilium continuing behind ear-coverts to join broad white line from lores; thin weak malar stripe of dark brown streaks and spots; white chin, throat faintly streaked brown; blackish-brown upperparts barred whitish or brownish-white, bars more irregular or spot-like on mantle; deep brown wings barred white, bars more as spots on wing-coverts; uppertail brownish-black, all feathers narrowly but distinctly barred white; white below, tinged pale yellow or buff, breast and flanks streaked dark brown, lower belly and flanks sometimes with

hint of barring; whitish undertail-coverts with fine brown spot-like streaks; longish bill straight, slightly chisel-tipped, black, paler base and lower mandible; iris deep brown to reddish; legs pale greyish. Differs from extremely similar *P. lignarius* in slightly smaller size, slightly paler appearance, broader white bars above, less heavy markings below. Female lacks red on nape and pale streaks on crown, occasionally has slight streaking on forehead. Juvenile duller and darker than adult, with barring above usually broken, dull white and more heavily streaked and barred below, both sexes with red on crown (not nape), red area smaller on female. Race *cancellatus* is rather distinctive, much browner, less black, with crown distinctly browner, white bars above broader than dark ones, much whiter below with far fewer and smaller streaks; *berlepschi* resembles nominate, but bill tends to be longer, brown areas somewhat darker, dark ear-covert patch bigger, ground colour of underparts cleaner white; *malleator* is like previous, but generally more heavily streaked below, usually some bars on flanks. VOICE. Single "peek"; also trilling "ti-ti-ti-ti-ti..." as long-distance call, and "we-we-we...". Drums.

**Habitat.** Inhabits various types of rather humid open woodland and riparian growth; also savanna woodland, and open *cerrado* woodland; in S of range, *berlepschi* occurs in arid bush country with spiny mesquite (*Prosopis*) species. Generally found in lowlands; recorded up to 610 m in Bolivia.

**Food and Feeding.** Insects, seeds. Forages singly or in pairs. Most common foraging substrates are twigs and small branches of bushes and trees. Main techniques are gleaning and probing; also pecks weakly.

**Breeding.** Sept-Nov. Nest excavated by both sexes, at 3-6 m in tree or palm. Clutch 4 eggs; no information on incubation and fledging periods.

**Movements.** Insufficiently known. Some post-breeding movement in S: Mato Grosso birds leave in May, and return in Jan.

**Status and Conservation.** Not globally threatened. No data on numbers. Probably quite common, but appears to be very local, for reasons not understood. Present in Serra do Cipó, Chapada dos Guimarães and Brasília National Parks (Brazil) and also Chancani Provincial Park and Ribera Norte Reserve (Argentina).

**Bibliography.** Belton (1984), Brooks, D.M. (1997), Brooks, T.M. *et al.* (1993), Canevari *et al.* (1991), Chebez *et al.* (1999), Contreras (1980b), Contreras *et al.* (1990), Dubs (1992), Ejlsdå & Krabbe (1990), Gore & Gepp (1978), Hayes (1995), Klimaitis & Moschione (1987), López (1997), López de Casenave *et al.* (1998), Marelli (1919), Mazar Barnett (2001a), Mazar Barnett & Pearman (2001), Mazar Barnett & Kirwan (2001), Melo-Júnior (2001a), Miserendino (1998), Narosky & di Giacomo (1993), Nellar (1993), Norez *et al.* (1983), de la Peña (1994), Praderi (2000), Remsen & Traylor (1989), Short (1970c, 1975, 1985b), Sick (1993), Souza (1999), Stotz *et al.* (1996), Tubelis (2000), Tubelis & Cavalcanti (2001), Wetmore (1926), Willis & Oniki (1990), Winkler & Short (1978).

## 112. Nuttall's Woodpecker

*Picoides nuttallii*

French: Pic de Nuttall      German: Nuttallspecht      Spanish: Pico de Nuttall

**Taxonomy.** *Picus Nuttallii* [sic] Gambel, 1843, Los Angeles County, California.

Forms ■ superspecies with *P. scalaris*, both being closely related to *P. pubescens*. Hybridizes occasionally with both. Monotypic.

**Distribution.** N California S (mainly W of desert areas) to NW Baja California.

**Descriptive notes.** 19 cm; 28-47 g. Male has black forehead and forecrown contrasting strongly with white nasal tufts, forecrown well streaked with white, red hindcrown and nape normally with a few white spots, black hindneck; black ear-coverts bordered above by white supercilium which curves down on to rear neck side, bordered below by white stripe backwards from lores; thin black malar stripe expands on neck sides into large patch, this joining with rear ear-coverts and also extending back to mantle side; white chin and throat; black upperparts, lower mantle to upper rump broadly barred white, wing-coverts spotted

white, flight-feathers narrowly barred white; uppertail black, white outer feathers often with 1 or 2 black spots, next 2 inner feathers barred black and white at tips; white below, lightly tinged cream-buff, breast side spotted, flanks, lower belly and undertail-coverts more barred; fairly long bill straight, chisel-tipped, blackish-grey to dull greyish-horn, paler base and lower mandible; iris deep brown; legs greyish or grey-olive, sometimes dark horn. Differs from *P. scalaris* mainly in having less red on head, more black on head and neck side, whiter underparts. Female has forehead to nape black, occasionally with some white spots on fore and rear areas, rarely entire head top white-streaked. Juvenile duller and less contrastingly patterned than adult, with more extensive pale (but greyer) areas above, dull buff to greyish below with more diffuse spots and more obvious bar marks, male with white-speckled red on crown centre, female with smaller and more broken red patch. VOICE. Double "pitii" or single "pit" calls, sometimes followed by a rapid low rattle, "ititititititit"; also "kweck", "tew-tew-tew" and other calls. Both sexes drum, with rolls relatively long, averaging 1-06 seconds.

**Habitat.** Arid to mesic woodland. Primarily open oak (*Quercus*) woodland, also riparian woodland, chaparral; more rarely conifer forest; suburbs. From sea-level to 1250 m, locally to 1700 m, rarely 2000 m.

**Food and Feeding.** Mainly insects and other arthropods: predominantly beetles (mainly Cerambycidae, Elateridae), also hemipterans, caterpillars, ants; also termites (Isoptera), millipedes (Diplopoda), Diptera, Neuroptera, spiders. Berries, seeds, acorns and nuts play a lesser role in diet; also visits sap wells made by *Sphyrapius*. Forages singly. Most foraging is in oaks and other trees (e.g. *Populus*, *Salix*) with dense foliage; also in mesquite (*Prosopis*) and yuccas (*Yucca*); occasionally on ground. Common feeding techniques gleaning and probing, also tapping; excavates only rarely, and flycatches occasionally. Seasonal and sexual differences more or less well expressed; males forage at lower levels, on larger branches, and tap more than do females.

**Breeding.** Season starts in Feb, egg-laying mostly in Apr-May, rarely to Jun. New nest-hole excavated each year, mostly by male, at 1-14 m (average 5 m) in dead tree stub or branch, or in fence post; hole entrance averages 5 cm across, cavity depth 28 cm. Clutch 3-6 eggs, usually 4 or 5; both sexes incubate, period recorded for only 1 nest, 14 days; both also feed chicks, rate of 6-3 feeds per hour in first week, 7-2 per hour thereafter; nestling period 15 days; fledglings remain with parents for c. 2 weeks. First breeding probably at 1 year.

**Movements.** Resident; some altitudinal movement. Casual records outside breeding range in California, and to N & W (S Oregon, and possibly Arizona), related to post-breeding dispersal.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in California EBA. Fairly common to common. Total population roughly estimated at c. 100,000-200,000 individuals, though numbers possibly rather lower; density of 20-1 pairs/km<sup>2</sup> in one study in San Bernardino County. No obvious trends detected. Relatively poorly known for a North American species; research required on its breeding biology.

**Bibliography.** Anon. (1998b), Baicich & Harrison (1997), Bent (1939), Block (1991), Browning & Cross (1994), Dodenhoff *et al.* (2001), Howell & Webb (1995), Jenkins (1979), Johnson (2000), Kaufman (1996), Koenig (1986, 1987), Lowther (2000), Manolis (1987), Miller & Bock (1972), Price *et al.* (1995), Root (1988), Short (1965c, 1969a, 1971c), Small (1994), Stark *et al.* (1998), Stotz *et al.* (1996), Unitt (1986), Wilbur (1987), Winkler & Short (1978), Zusi & Marshall (1970).

## 113. Ladder-backed Woodpecker

*Picoides scalaris*

French: Pic arlequin      German: Texasspecht      Spanish: Pico Mexicano

**Taxonomy.** *Picus scalaris* Wagler, 1829, central Veracruz, Mexico.

Forms a superspecies with *P. nuttallii*, with which it occasionally hybridizes; also closely related to *P. pubescens*. Has possibly interbred also with *P. villosus*. Considerable individual and some clinal variation; described races *centrophilus* (W Mexico), *azelus* (S Mexico), *symplectus* (SE Colorado and W Oklahoma S to NE Mexico), *giraudi* (EC Mexico), *ridgwayi* (SE Veracruz) and *percus* (Chiapas) regarded as indistinguishable. Eight subspecies recognized.

**Subspecies and Distribution.**

*P. s. cactophilus* (Oberholser, 1911) - SW USA, from SE California, S Nevada, SW Utah, SE Colorado, W Oklahoma and W Texas, S to NE Baja California and S in C Mexico to Michoacán and Puebla.  
*P. s. eremicus* (Oberholser, 1911) - N Baja California.  
*P. s. lucasanus* (Baird, 1859) - S Baja California.  
*P. s. sinaloensis* (Ridgway, 1887) - coastal W Mexico from S Sonora S to Guerrero, SW Puebla and C Oaxaca.  
*P. s. graysoni* (Baird, 1874) - Tres Mariás Is, off W Mexico.  
*P. s. scalaris* (Wagler, 1829) - Veracruz and Chiapas.  
*P. s. parvus* (Cabot, 1845) - N Yucatán Peninsula, including Cozumel I and Holbox I.  
*P. s. leucopitillus* (Oberholser, 1911) - Belize, Guatemala and El Salvador to NE Nicaragua.

ted with white, flight-feathers white-barred; uppertail black, outer 2 feathers barred white, adjacent pair barred at tip; pale buffish-white below, breast sides (sometimes also centre) and upper flanks finely streaked dark, lower flanks and undertail-coverts with spot-like bars; long bill rather straight, chisel-tipped, blackish to dark brown-grey or grey, paler base and lower mandible; iris brown to red-brown, sometimes dull red; legs greyish-olive. Distinguished from *P. nuttallii* by having more red on crown, less black on head and neck, more numerous pale bars above and on outer tail, more buffy underparts with smaller dark streaks. Female has crown to nape black, sometimes with a few white spots on forehead. Juvenile duller than adult, barring above diffuse, generally more buff below with heavy dull brown streaks and more barring, both sexes with white spots on forehead, red patch in crown centre, patch usually smaller on female. Race *cactophilus* is larger than nominate, has blacker forehead, complete black malar, white bars on upper mantle, variably broader pale bars on back, paler underparts with spots rather than streaks, sometimes all-white outer rectrix; *eremicus* is larger, longer-tailed and longer-billed than previous, has thinner pale bars above, darker face and underparts, stronger dark bars on lower underparts; *lucasanus* is smaller and whiter than last, with white bars above broader, underparts paler; *graysoni* resembles previous, but slightly smaller and shorter-tailed, and more buff (less grey-brown) below with thinner streaks on breast side; *sinaloensis* is medium-sized, usually with malar interrupted towards bill, has dark face and underparts, latter streaked rather than spotted; *parvus* is smaller and darker than nominate, has black forehead, more black in malar, broader black bars above, spotted rather than streaked below, belly more obviously barred; *leucopitillus* is smallest, just smaller than previous, with more white in upperparts, darker and buffier below with little spotting on breast, relatively indistinct barring on lower belly. VOICE. Single "peek", often repeated in alarm; accelerating series e.g. "cheekcheekcheekcheek", dropping in pitch at end. Drums infrequently, rolls short and fast.

**Habitat.** Very arid country and deserts; open to semi-open woodland and woods along (seasonally dry) rivers, with deciduous trees or cacti; also pine (*Pinus*) woods and pine mixed with oak (*Quercus*) in Central America. Also locally in clearings of humid forest, and in mangroves in El Salvador and

Honduras. From lowlands to 2300 m in USA; at 1500-2100 m, rarely to 2600 m, in NE Mexico, and to 3000 m in Baja California; to 1800 m in Guatemala.

**Food and Feeding.** Mainly insects, some other arthropods. Larvae and adults of beetles; also caterpillars, ants and hemipterans. Also takes fruit. Forages singly, occasionally in pairs. Seeks food on trunks and branches of broadleaved and coniferous trees, mesquite (*Prosopis*), bushes, yuccas (*Yucca*) and cacti; rarely on ground. Foraging generally varies with location and season. Sexes differ in use of plant species, females spending more time in bushes and mesquite; females also utilize smaller branches and twigs more, and excavate less. Surface-oriented techniques, i.e. gleaning, probing, removing of bark or debris, predominant; excavating is uncommon.

**Breeding.** Laying recorded Mar-Jul, normally Apr-Jun. Flutter-aerial display and other typical displays. Nest excavated at c. 1-9 m in dead part of tree, stub, often in yucca, agave (*Agave*), sometimes large cactus, or in fence post or utility pole; entrance hole c. 4 cm across, cavity depth 18-36 cm. Clutch 2-7 eggs, usually 3-5, clutches smaller in S; both sexes incubate eggs and feed young; incubation and fledging periods not recorded. First breeding probably at 1 year. Longevity in wild 4-5 years.

**Movements.** Resident and sedentary.

**Status and Conservation.** Not globally threatened. Fairly common in USA; common to fairly common in Mexico. Estimated density 1-15 birds/40 ha in one study area in S California. Long-term decline since 1960's in Texas. Preference for very arid habitats makes this species less likely to come into contact with humans; locally, could suffer some degradation or loss of habitat through livestock grazing.

**Bibliography.** Anon. ## 114. Downy Woodpecker

*Picoides pubescens*

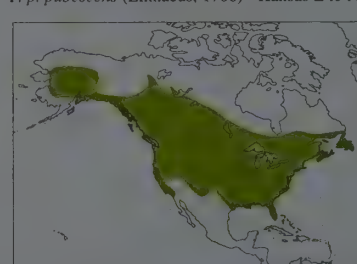

French: Pic mineur      German: Dunenspecht      Spanish: Pico Pubescente

**Taxonomy.** *Picus pubescens* Linnaeus, 1766, South Carolina, USA.

Most closely related to *P. nuttallii* and *P. scalaris*, and has hybridized with former. DNA analyses also indicate possible relationship with *Dendrocopos minor* of Old World; further study required. Nominate race and *medianus* intergrade widely in C USA. Clinal variation in size, decreasing from N to S. Additional named races *nelsoni* (Alaska to Alberta) and *microleucus* (Newfoundland) considered unacceptable. Six subspecies recognized.

**Subspecies and Distribution.**

*P. p. medianus* (Swainson, 1832) - C Alaska and Canada (E of Rockies, from S Mackenzie and Alberta) E to S Quebec and Newfoundland, and S in USA to Nebraska and Virginia.  
*P. p. glacialis* (Grinnell, 1910) - SE Alaskan coast.  
*P. p. gairdnerii* (Audubon, 1839) - W British Columbia S along coast to NW California.  
*P. p. leucurus* (Hartlaub, 1852) - Rocky Mts from SE Alaska S to NE California, Arizona and New Mexico.  
*P. p. turati* (Malherbe, 1861) - inland Washington and Oregon, and California (except NW & NE).  
*P. p. pubescens* (Linnaeus, 1766) - Kansas E to North Carolina and S to E Texas and Florida.

**Descriptive notes.** 15-17 cm; 20-7-32-2 g, mean 27-0 g. Male has whitish nasal tufts, black forehead to hindcrown, red nape, narrowly black hindneck; white supercilium from above eye, broadening at rear to meet nape; black ear-covert patch extending up to lower nape; white lores and broad cheekband, becoming broad white patch on rear neck side, bordered below by black malar stripe (often broken near bill) which continues back to mantle side; white chin and throat; black upperparts except for white central panel from mid-mantle to lower back, wing-coverts with large white subterminal spots, flight-feathers with spots on outer webs and bars on inner webs; uppertail black, all but central feather pair with white at tip, white increasing in extent outwards, outer pair mostly white with variable but often prominent black bars; white to greyish-white below, undertail-coverts sometimes with faint streaks or spots; short bill almost straight, slightly chisel-tipped, dark grey or blackish, paler base and lower mandible; iris deep brown or red-brown; legs olive-grey or grey. Differs from *P. villosus* in clearly smaller size, much smaller and shorter bill, black-barred outer tail, malar not extending to breast side. Female has nape black or white-streaked black. Juvenile has black areas browner, white of back streaked darker, greyish or buffish underparts finely streaked on breast and flanks, variably barred on lower flanks, greyish or olive eyes, male with red feather tips on crown (but not nape) and variable white spotting on forehead, female with crown brownish-black and either unmarked or lightly or heavily streaked pale. Races differ mainly in size, amount of white in wings, and tone of underparts: *medianus* is larger and paler than nominate; *leucurus* is largest and whitest, with few or no white wing-covert spots, little black in outer tail, pure white below with undertail-coverts unstreaked; *glacialis* is very like previous but more pale buffish-white below, with more dark bars in outer tail; *gairdnerii* has wing-coverts largely unspotted, outer tail strongly barred, is darkest below, brownish-grey to buff; *turati* is smaller than previous, with slightly paler, pale buffish-grey, underparts. VOICE. Single "pik" notes, sometimes at high rates in alarm; characteristic series of notes, dropping in pitch at end, "peet-peet-peet-peet-peet-pit-pit-pit". Drums in short rolls.

**Habitat.** Deciduous and mixed forest, woodland, second growth, parks and gardens, including in suburban and urban areas. Partial to riverine woodland in SW & S parts of range; prefers moist aspen (*Populus tremula*) and willow (*Salix*) stands in coniferous zone. From sea-level to hills; 1860-2750 m in SW mountains.

**Food and Feeding.** Mainly insects, some vegetable matter. Wood-boring larvae an important component; beetles and ants each form about a third of the diet; other animal items include bugs (Hemiptera), plant lice, Diptera, caterpillars, grasshoppers (Acrididae), spiders and myriapods. Bark beetles (*Scolytus*), spiders, ants and moths fed to nestlings. Various types of berries taken when available; seeds and nuts become more important in winter. Forages singly or in pairs; commonly joins mixed-species flocks, especially with tits (Paridae). Visits garden feeders, especially in winter. Foraging rather flexible, and substrate use changes with season, supply, and competition. Live

wood usually selected, but occasionally species shifts completely to dead trees, including fire-killed ones. Generally, limbs of small diameter (less than 25 cm) are preferred, and foraging may take place at all heights in a tree, with some emphasis on lower canopy; also descends to fallen logs. Larger trees and those with more furrowed bark are favoured in winter. Male concentrates more on upper levels, maintaining this segregation through supplanting attacks on female. Pecking is commonest technique, followed by hammering and probing; bark and wood are not deeply excavated; also, some flycatching in summer. Commonly removes bark, and on dead trees in particular this may amount to more than half of foraging activity.

**Breeding.** Egg-laying in Apr-May in Florida, in May-Jul in British Columbia; may rear more than 1 brood within a season. Flutter-aerial displays mainly by male; nape feathers erected during courtship. Nest-excavation completed within 13-20 days, hole in dead tree or in dead part of tree, often located just beneath broken-off top of a stub, or in fence post or utility pole. Clutch 3-7 eggs, usually 4 or 5, mean 4.81, clutch size tending to increase with latitude (to 7 eggs in British Columbia); male and female share all breeding duties, incubation, brooding, feeding, nest sanitation, female often reducing her effort towards end of nestling period; incubation period 12 days, nestling period 20-23 days; fledglings accompanied by parents for up to 3 weeks.

**Movements.** Resident in most of range. N and montane populations partially migratory or disperse over longer distances, some individuals moving as far as 1200 km away from breeding grounds; stragglers recorded S to NW Mexico.

**Status and Conservation.** Not globally threatened. Common to very common; the commonest woodpecker in many parts of range. Populations generally stable, with some local increases; adaptable, able to exploit human-altered habitats. Benefits from opening-up of forest and creation of second-growth habitats.

115. Red-cockaded Woodpecker  
*Picoides borealis*

**French:** Pic à face blanche      **German:** Kokardenspecht      **Spanish:** Pico de Florida

**Taxonomy.** *Picus borealis* Vieillot, 1807, Mount Pleasant, South Carolina, USA. Basal relationships with *P. stricklandi*, *P. villosus* and *P. albolarvatus*. Birds from C & S Florida named as race *hylonomus* on basis of smaller size, but unacceptable, since size decreases clinally from N to S. Monotypic.

**Distribution.** Patchily in SE USA, from SE Oklahoma and E Texas E to Atlantic coast; extends N to Kentucky and S Virginia, S to C Louisiana, S Mississippi and C Florida.

ing base on outer tail, dark bars or half-bars on outer 2 feathers; white underparts often sullied buffish or pale grey, large black spots and streaks on breast side, becoming smaller or narrower on flanks, sometimes thin bars on lower flanks and undertail-coverts; fairly long bill chisel-tipped, culmen slightly curved, blackish-grey; iris dark brown; legs olive-grey. Female lacks red spot at nape side. Juvenile duller and browner above than adult, with dusky cheek patch, duller and more diffusely marked below, male also with dull reddish crown centre. **Voice.** Commonest call in human presence and alarm a distinctive "shrit" or "sklit", singly or in groups or series, depending on context; much rarer is preamble of call-like notes followed by up to 30 notes that are shorter and lower-pitched versions of call, also in shorter and more variable form by fledged young; groups rather vocal, frequently a wide range of twittering calls and chortles varying from low and short to clear "wica-wica-" notes, may be combined with call notes; low soft notes in intimate contacts, especially at nest or roost; nestling calls change considerably during course of chick development. Drumming infrequent, by both sexes, not particularly loud.

**Habitat.** Adapted to open mature pine (*Pinus*) forest and forests of pine mixed with oak (*Quercus*), requiring open pine stands with a park-like structure for nesting. Also uses adjacent stands of cypress (*Taxodium*), cornfields and orchards for foraging. Nesting on a few species belonging to the "longleaf pine savanna" of the SE USA: primarily longleaf pine (*P. palustris*), slash pine (*P. elliotii*), shortleaf pine (*P. echinata*), also loblolly pine (*P. taeda*), pitch pine (*P. rigida*) and pond pine (*P. serotina*), all of which meet the species' particular nest-site requirements. Old-growth forest very important as a high-quality foraging habitat. Restricted to Atlantic coastal plain and hills below 500 m.

**Food and Feeding.** Diet mainly insects, their larvae, and other arthropods; some plant material. Ants, particularly eggs, larvae, pupae, also adults of arboreal *Crematogaster*, are most important, forming up to 80% of diet (annual average c. 50%), followed by adults and larvae of wood-boring beetles (*Dendroctonus frontalis*, *Ips*, 15%); other insect larvae, Hemiptera, wood roaches (Blattodea), termites (Isoptera), other beetles, hymenopterans, moths, damselflies (Zygoptera), spiders, scorpions (Scorpiones), centipedes (Chilopoda), and millipedes (Diplopoda) also recorded as food. Male's diet contains higher proportion of ants. Nestling food mainly spiders, ants, beetles and their larvae, centipedes, as well as carpenter-bees (Xylocopidae) and miscellaneous other arthropods and larvae. Fruits (e.g. cherries) and berries of various species (e.g. *Vaccinium*, *Myrica*) taken to some extent, even fed to nestlings; pine seeds taken mainly in winter; other plant food includes nuts (*Carya*). Females observed to cache bone fragments during egg-laying period. Roams through territory singly, in pairs or in groups; accompanies mixed-species foraging flocks in winter. Pines are main tree species utilized (90% of foraging), with larger (older) ones preferred, but hardwood and other trees and orchards also exploited; cornfields entered when infested with earworms (*Heliothis*). Live and dead trees visited about equally, although local differences seem to exist, with live and only recently dead pines preferred in some places. Most foraging is on tree trunks; males, which feed more often on limbs, frequently move along underside of branches. Clear sexual differences, most pronounced in Jan-Mar: males use mainly upper trunk and branches, females tend to feed on lower trunk, sexes overlap greatly in use of mid-trunk; consequently, sexes differ in foraging height by c. 3-7 m. Food frequently obtained by removing bark, achieved by grasping pieces with the bill, by prying it off, and often by grabbing bark with both feet and making short flying leap or by scratching with both feet; exposed prey then gleaned. Scaled trees give away species' presence. Also probes crevices and needle and cone clusters; males, in particular, sometimes peck to excavate decayed wood. Occasionally makes aerial sallies to catch flying insects.

**Breeding.** Lays in late Apr; rarely, 2 broods. In pairs; a third of these have helpers, 70-95% of which are males, generally offspring from previous broods; once established, such breeding units are sedentary, or at least breeding male; when male dies or when forced out by group-members or intruders, female may break away from unit. Nest-hole excavated mostly 10-13 m above ground in mature pine, entrance 5.7-7.1 cm wide with slightly upward-inclined tunnel up to 6 cm long in sapwood, nest-chamber excavated in rotten heartwood and at least 17-18 cm deep with diameter 9-10 cm; nest is breeding male's roost; nest-site highly distinctive, with sap flowing from holes drilled around entrance and much bark removed from trunk. Clutch 2-5 eggs, usually 3 or 4; incubation begins with last or next to last egg, shared by both members of pair about equally during day, sometimes a helper also incubates, breeding male stays in nest overnight, incubation period 10-11 days, occasionally to 13 days; chick hatches blind and naked, with bright pink skin, by 4th or 5th day feather sheaths become visible, eyes open c. 10th day, nestlings stay at bottom of hole for 15 days; both parents feed nestlings, male helpers contribute as much to nest sanitation, brooding and brood-feeding as do parents, fledging weight of 42-45 g (males tend to be heavier) reached c. 3-4 days before leaving nest; nestling period 26-29 days, sometimes shorter (22 days); male and any helpers continue to feed young for 2-6 months. Usually 2 chicks reared.

**Movements.** Resident and sedentary. Stragglers recorded N to Ohio.

**Status and Conservation.** VULNERABLE. Uncommon to rare, and extremely local. Adapted to open mature pine and pine-oak forests, which form a unique ecosystem in SE USA that is found primarily on federal and state lands. Estimated population in 2000 no more than 10,000 mature adults, concentrated in c. 30 sub-populations, largest in Carolinas and N Florida. Recently became extinct in Maryland, imminent extinction seems likely in Tennessee, few remain in Kentucky, and populations continue to decline elsewhere. Strict habitat requirements led to dramatic decline in numbers in 20th century, with reduction by at least 23% during 1980's alone; decline caused primarily by extreme fragmentation of habitats resulting in concentrations of breeding groups. A clan of 3 or 4 birds requires c. 58-91 ha of suitable habitat for its survival; genetically healthy populations possibly require more than 25,000 ha. Habitat fragmentation, clear-cutting and mid-storey encroachment of hardwood are major causes of the decline of this species, which also suffers locally from devastating effects of hurricanes; irregular shelterwood-cutting seems to be less detrimental. Dense hardwood mid-storey is generally detrimental, but there seem to be regional differences in negative effects of hardwood admixture; up to 52% non-pine species have been registered in Kentucky habitats. Numerous conservation strategies have been employed in recent decades, some more successful than others, some having had adverse effects. Since start of habitat management in 1988, infestations of nesting trees by southern pine beetle (*Dendroctonus frontalis*) have increased; beetles infest nest-holes and kill trees used for nesting. Management should ensure sufficient number of mature trees for replacement holes, and old trees for foraging. Optimum habitats assume their typical structure through frequent fires, to which the pines are well adapted; prescribed fires (best during Mar-Apr) to control woody mid-storey vegetation are the most commonly used management tool to restore the pine-grassland communities that are important for this species; such measures need to be properly regulated.

## 116. Strickland's Woodpecker

### *Picoides stricklandi*

**French:** Pic de Strickland **German:** Stricklandspecht **Spanish:** Pico de Strickland  
**Other common names:** Brown-backed Woodpecker(!); Arizona Woodpecker (*arizonae*/*fraterculus*)

**Taxonomy.** *Picus* (*Leuconotopicus*) *Stricklandi* Malherbe, 1845, Mount Orizaba massif, Veracruz, Mexico.

Closest to *P. borealis*, *P. villosus* and *P. albolarvatus*. Races *arizonae* and *fraterculus* originally treated as together forming a separate species, *P. arizonae*, subsequently lumped into present species, but recently resplit by several authors: distinctive morphological differences suggest that separation into two species is perhaps tenable, although vocalizations apparently very similar, plumage differences perhaps clinal in nature, and ecological requirements of the two groups overlap; further research needed. Birds from SE Sinaloa E to W Zacatecas and S to S Jalisco separated as race *websteri*, but apparently only an intermediate form between *arizonae* and *fraterculus*; also, birds from C Mexico (E Michoacán to Distrito Federal) named as race *aztecus*, being less heavily marked below than nominate, but this character apparent only in very fresh plumage and also subject to clinal variation, degree of streaking increasing towards E. Three subspecies recognized.

#### Subspecies and Distribution.

*P. s. arizonae* (Hargitt, 1886) - SE Arizona, extreme SW New Mexico, and Mexico in Sierra Madre Occidental (S to NE Sinaloa and neighbouring parts of Durango).

*P. s. fraterculus* (Ridgway, 1887) - S Sinaloa and adjacent Durango S to Michoacán.

*P. s. stricklandi* (Malherbe, 1845) - E Mexico, from E Michoacán E to WC Veracruz and Puebla.

**Descriptive notes.** 18-20 cm; 34-51 g. Male has buff nasal tufts, blackish-brown forehead and crown, red nape, blackish-brown hindneck; white stripe behind eye; dark brown upper lores and ear-coverts, white cheekband broadening behind ear-coverts and continuing down rear neck side; blackish malar stripe broadening on neck side, extending to uppermost breast side; white chin and throat variably spotted; blackish-brown upperparts barred greyish from back to rump, flight-feathers with small white spots forming indistinct bars on inner webs, small spots on outer webs of primaries; uppertail dark black-brown, outer 2 or 3 feather pairs barred

white; whitish below, breast heavily marked with blackish spots, more barred on flanks and lower underparts; longish bill straight, chisel-tipped, blackish, paler base and lower mandible; iris dark brown; legs greenish-grey. Female has nape black-brown, not red. Juvenile duller than adult, has less white on neck side and tail, is darker below with heavier markings and much barring, both sexes with orange-red on crown, usually restricted to hindcrown on female. Races differ from nominate in much paler upperparts without barring, clearly longer bill: *arizonae* has all dark parts of head and upperparts medium to darkish brown, rather than blackish-brown, mantle to rump usually unmarked but occasionally with hint or more of pale bars, often more obvious white in outer tail; *fraterculus* is very similar, but slightly smaller and darker. **Voice.** Single "peep"; distinctive rattle, "peep chree-chree-chree-chree". Both sexes, mainly male, loud longish rolls; signal-tapping at prospective nest-site.

**Habitat.** In N of range (Arizona) and W Mexico, mixed subtropical pine-oak (*Pinus-Quercus*) woodland, also riparian woodland with sycamore (*Platanus*) and walnut (*Juglans*); almost entirely pine woods in SE; at 1200-2400 m. In C & E Mexico, nominate race inhabits temperate coniferous forest in higher mountains of C volcanic belt, in woods dominated by pines, mixed with firs (*Abies*), oaks, cypresses (*Cupressus*) and alders (*Alnus*), at 2500-4100 m (Veracruz, Puebla).

**Food and Feeding.** Insects, mainly beetle larvae, and some fruits and seeds (acorns). Forages mainly on pines; less selective during breeding season. Usually singly; joins mixed-species feeding flocks. Forages mostly from middle to low levels, on trunks, branches and twigs; female more on twigs, especially in breeding season. Trunk-foraging clearly predominates during early spring, at which time pecking and hammering (to excavate or to remove bark, which is also removed with feet) are most common techniques, followed by probing, gleaning and flycatching. Surface-feeding more common in summer.

**Breeding.** Mainly from Apr-May. Displays include head-swinging, wing-spreading and flutter-aerial display. Nest excavated at 2-4-15 m, mostly at about 3-6 m, in dead tree or dead part of tree, or in agave (*Agave*) stem; hole entrance 5-5.7 cm across, cavity depth 30-38 cm. Clutch 2-4 eggs; both sexes incubate, period uncertain, 14 days or probably fewer; both also feed chicks, male more than female, fledging period 24-27 days; juveniles accompanied and fed by parents for 2-3 weeks. Fledging success averaged 1-8 at five nests in Arizona; youngest chick often starves.

**Movements.** Resident. Periodic downslope movements after breeding recorded in SE Arizona, possibly in response to food shortage.

**Status and Conservation.** Not globally threatened. Generally uncommon throughout range, though locally quite common. Densities low: 4 pairs/40 ha in oak-juniper-pine woodland and 1 pair/40 ha in oak woodland in SE Arizona; 1-5 pairs/1-6 km in linear censuses in pine-oak woodland in SW USA and NE Mexico; in Huachuca Mts (SE Arizona), more than 1 bird/10 ha recorded in riparian habitats in both summer and winter. Populations possibly threatened locally because of habitat fragmentation and loss; heavy grazing may have important local effects.

**Bibliography.** Anon. (1998b), Bent (1939), Corcuera & Butterfield (1999), Davis (1965), Howell & Webb (1995), Hutto (1992), Kaufman (1996), Koenig (1986, 1987), Ligon (1968a, 1968b), Manolis (1987), Marshall (1957a, 1957b), Moore (1946), Morris & Buffa (1996), Peterson & Navarro-Sigüenza (2000), Price *et al.* (1995), Root (1988), Schladach (1963), Spofford (1977), Stotz *et al.* (1996), Wilson & Ceballos-Lascuráin (1993), Winkler (1979a), Winkler & Short (1978).

## 117. Hairy Woodpecker

### *Picoides villosus*

**French:** Pic chevelu

**German:** Haarspecht

**Spanish:** Pico Velloso

**Taxonomy.** *Picus villosus* Linnaeus, 1766, New Jersey, USA.

Related to *P. stricklandi* and *P. albolarvatus*, with which it forms a relatively closely related cluster of species that is linked with *P. borealis*. May have interbred with *P. scalaris*. Molecular-genetic analysis suggests very close relationship to *Veniliornis fumigatus*, perhaps to extent that the two could justifiably be treated as congeneric; further study needed. Spectacular variation in size, coloration and plumage pattern is largely clinal in nature, associated with temperature and moisture, with races intergrading in many areas. A large number of races have been described, of which many are unsustainable: *monticola* (Rocky Mts from British Columbia to New Mexico), *leucothorectis* (mountains of SW USA), *scrippsae* (N Baja California), *intermedius* (E Mexico), *parvulus* (N El Salvador to N & W Honduras), *fumeus* (highlands of S Honduras and N Nicaragua), *extimus* (highlands of Costa Rica and Panama). Fourteen subspecies currently recognized.

#### Subspecies and Distribution.

*P. v. septentrionalis* (Nuttall, 1840) - from tree-line in Alaska E across S Canada to Ontario, and S to SC British Columbia, Colorado, N New Mexico, Montana and North Dakota.

*P. v. villosus* (Linnaeus, 1766) - from E North Dakota E to S Quebec and Nova Scotia, and S to E Colorado, C Texas, Missouri (Ozark Plateau) and N Virginia.

*P. v. terraenovae* (Batchelder, 1908) - Newfoundland.

*P. v. sitkensis* (Swarth, 1911) - coast of SE Alaska and N British Columbia.

*P. v. piceoides* (Osgood, 1901) - Queen Charlotte Is., off British Columbia.

*P. v. harrisi* (Audubon, 1838) - coastal region from S British Columbia to NW California.

*P. v. audubonii* (Swainson, 1832) - from E Texas, S Illinois and SE Virginia S to Gulf coast.

*P. v. hyloscopus* (Cabanis & Heine, 1863) - W California S to N Baja California.

*P. v. orius* (Oberholser, 1911) - Cascade Mts in British Columbia S through C Oregon to SE California, C Arizona, New Mexico and extreme W Texas.

*P. v. icastus* (Oberholser, 1911) - SE Arizona and SW New Mexico S in W Mexico to Jalisco.

*P. v. jadinii* (Malherbe, 1845) - C Mexico from San Luis Potosí, Tamaulipas and Veracruz to Jalisco, Guerrero and Oaxaca.

*P. v. sanctorum* (Nelson, 1897) - S Mexico (Chiapas) and Guatemala SE to W Panama.

*P. v. piger* (G. M. Allen, 1905) - N Bahamas (Grand Bahama, Abaco, Mores).

*P. v. maynardi* (Ridgway, 1887) - S Bahamas (Andros, New Providence).

**Descriptive notes.** 16.5-26 cm; 59-80 g (*villosus*), 72-80 g (*piceoides*), 42 g (*sanctorum*). Male has white nasal tufts, black forehead and crown, narrow red to orange-red nape patch, black hindneck; white supercilium from above eye to nape; small black area in front of eye and broad black band through ear-coverts to nape; white lores, wide white band below eye and ear-coverts and broadly down rear neck side; black malar stripe usually partly obscured by white near bill, expanding on neck side and continuing back to mantle and down to upper breast side; white chin and throat; black sides of mantle and back, contrasting

broad white central panel from mid-mantle to lower back, black rump and uppertail-coverts; black wings, coverts with large white subterminal spots, flight-feathers barred white; uppertail black centrally, white tips on rest of feathers, with extent of white increasing outwards so that outermost feathers are all white; white with very slight grey tinge below, rarely with a few streaks on breast side below malar extension or faint streaks on flanks; long bill chisel-tipped, culmen slightly curved, dark grey to blackish, paler base and lower mandible; iris deep brown or red-brown; legs grey or blue-grey, sometimes darker or green-tinged. Differs from *P. pubescens* in larger size, distinctly longer more powerful bill, unbarred white outer tail, black band from neck side to upper breast. Female has nape black or mixed black and white. Juvenile duller than adult, black areas browner, underparts somewhat darker with at least some streaks or bars, some bars on outer tail, greyer eyes, white eyering, male with orange or red patch on crown, normally much smaller on female. Races differ considerably in size, plumage coloration and pattern, largest and palest in N and in cold dry climates, white in wing reduced in W and S; *septentrionalis* is largest and whitest, large-billed, much white on head; *terraenovae* is greyer and buff-tinged below with fine flank streaks, has narrower white face stripes, narrower dark-streaked white back panel, less white in wing, often some bars on outer tail, juvenile buff below with well-streaked breast side, barred flanks; *audubonii* is smaller and darker than nominate, has greyish-buff underparts; *piceoides* has buff-brown face and underparts, pale of back barred dark, little white in wing, obvious streaking on flanks, barred outer tail; *sitkensis* is large, buffish below, has more white in wing than previous; *harrisi* is smaller than previous, with longer bill, pale parts of plumage grey-brown, white in wing very much reduced; *hyloscopus* is a trifle smaller than last, paler, more buff (less grey-brown) below, with whitish suffusion; *orius* is bigger than previous, relatively longer-billed, paler below; *icastus* has shorter wing and tail than last, much shorter bill, no pale wing-covert spots, darker buffer underparts; *jadinii* is smaller than previous, has pale head markings narrow, much darker (deep buff-brown) underparts with few streaks on breast side; *sanctorum* is even smaller, on average smallest of all races, with supercilium very narrow, darker below, sometimes pale flanks (especially in Nicaragua), streaks on breast side variable; *piger* also very small, with back slightly dark-streaked, white wing-covert spots, usually 1-2 dark bars in outer tail, has brownish throat, paler breast, dusky flanks streaked and barred; *maynardi* differs from previous in unstreaked back, plain white outer tail, paler unmarked underparts with buff tinge on breast. **Voice.** Rather high-pitched "keek"; calls of Panama birds higher-pitched and more subdued than in N, perhaps harsher in W North America than in E; also "keek kit-kit-kit-kit-kit" series. Both sexes drum, producing short rolls tending to slow down towards end; taps at nest.

**Habitat.** Wide range of forest types and woodlands, especially with pines (*Pinus*). In NW USA found in mixed forest with Douglas fir (*Pseudotsuga*) and western hemlock (*Tsuga heterophylla*), preferring former species for foraging; in W USA also in open juniper (*Juniperus*) woodland; in riparian forest in plains; virtually all types of forest in E North America. Mainly pine woods in Bahamas. Restricted to highlands in Mexico and Guatemala, in pine-oak forest and in oak and other broadleaved forest, cypress (*Cupressus*) stands, and second growth. In Costa Rica and Panama occurs in wet, epiphyte-laden highland forest up to stunted forest at timber-line, and in neighbouring clearings and semi-open areas; main abundance centred in oak forest of higher elevations. Also visits gardens, but less frequently than e.g. *P. pubescens*. In N parts of range occurs from sea-level to 2900 m in W mountains; usually above 2000 m in Arizona; recorded at 1000-

3700 m in Mexico, 900-2900 m in Guatemala; from 1200 m but mostly 1500-3400 m in Costa Rica and Panama.

**Food and Feeding.** Largely animal food; c. 50% of this made up by larvae of wood-boring beetles (especially cerambycids and buprestids, but also curculionids, scolytids, siricids and others), remainder consisting of caterpillars (even hairy ones) and other arthropods, e.g. spiders, millipedes (Diplopoda). Diet also includes fruits and seeds, mostly coniferous, particularly in winter; sap taken at *Sphyrapius* weils. S races seem to take more fruit and berries than do N ones, may even feed young with figs (*Ficus*); wild raspberries and blackberries and hardy fruits, such as cornel (*Cornus*) berries, and acorns eaten in summer, Virginia creeper (*Parthenocissus*) berries and apples in winter. Forages usually singly or in pairs; occasionally joins mixed flocks; may concentrate locally in areas where forest fires have occurred. Live and large trees generally visited more often, except during winter, although often forages on dead branches. Mean foraging height shifts seasonally, higher in winter: snags without branches more frequently visited in winter. Parts of trees below crown and without limbs are favoured foraging substrate. Visits Joshua trees (*Yucca brevifolia*) in California, and in Central America also utilizes bamboo (*Chusquea*), old stalks of giant thistle and stems of soft shrubs such as *Senecio*. Descends to ground, most frequently in early spring. Pecking and hammering are characteristic foraging techniques, by which bark is removed or funnel-shaped holes drilled into bark; also probes, and pries or tears off bark. Seasonal changes in foraging methods involve mainly increase in probing from winter to spring and parallel addition to the repertoire of gleaning and searching; pecking and hammering, very important in winter, are somewhat reduced in spring, but excavating by vigorous hammering and pecking comprise major foraging activities in all seasons. Male uses more subsurface-feeding than female.

**Breeding.** Season varies relatively little; nests found in Apr-Jun in British Columbia and Ontario, end Mar to Jun (peak Apr-May) in California, in Mar-Jul in Bahamas, and in Feb-Apr in Costa Rica; pair-formation starts 2-3 months before nesting. During courtship male erects red parts of nape feathering and spreads tail fully; flutter-aerial display, often with calls, in breeding period. Nest-excavation takes 17-24 days, nest-hole usually in live tree but in a dead section or in wood afflicted with fungal heart-rot, or in utility pole or fence post; sometimes in palm in Bahamas; may usurp hole of other woodpecker and enlarge it if necessary. Clutch 2-5 eggs, mean 3.93 in main part of range, decreasing to S, c. 3 eggs in Costa Rica; both sexes incubate and both feed nestlings, incubation period 14 days, nestling period 28-30 days; fledglings divided between parents, accompanied by adult for at least 2 weeks. First breeds probably at 1 year.

**Movements.** Resident in most of range. Some seasonal movements performed by populations farthest N, and highland populations move downslope in winter. Recorded as a vagrant in Puerto Rico (Mona I).

**Status and Conservation.** Not globally threatened. Fairly common in most of range; fairly common in Bahamas; rather common in Mexico. Rather widespread in much of range, especially where more adaptable in terms of habitat selection. Possibly subject to some threat locally through loss or degradation of habitat.

**Bibliography.** Askins (1983), Baldwin (1960), Beal (1895), Bent (1939), Binford (1989), Blackford (1955), Blake, E.R. (1965), Blake, H.E. ## 118. White-headed Woodpecker

### *Picoides albolarvatus*

**French:** Pic à tête blanche      **German:** Weißkopfspecht      **Spanish:** Pico Cabeciblanco

**Taxonomy.** *Leuconerpes albolarvatus* Cassin, 1850, Oregon Canyon, California. Closest to *P. borealis*, *P. stricklandi* and *P. villosus*. Races rather poorly differentiated, with variation possibly clinal. Two subspecies recognized.

#### Subspecies and Distribution.

*P. a. albolarvatus* (Cassin, 1850) - SC British Columbia S, discontinuously in mountains, to Washington, W Idaho, Oregon, California (S in Coast Ranges to NW Colusa, and along Sierra Nevada in E), and extreme W Nevada.

*P. a. gravirostris* (Grinnell, 1902) - SW California (mountains around Los Angeles and San Diego).

**Descriptive notes.** 24 cm; 50-79 g, mostly 52-68 g. Male has white forehead, crown, lores, side of head, and chin to upper breast, usually faint buff tinge on forehead, greyish tinge on crown; very thin dark line behind eye often obscured, red nape; hindneck, rear neck side, entire upperparts and underparts below breast black, upperparts, wing-coverts and breast slightly blue-glossed, most of primaries with white bases, on some extending almost to tip on outer web, central primaries with 2 or 3 small white spots near tip of outer web; black tail; sometimes isolated white feather edges visible on underparts; longish bill slightly curved, chisel-tipped, dark

grey; iris deep brownish-red or dull red; legs greyish-olive to grey. Female has nape black, not red. Juvenile much browner than adult, white wing patch somewhat larger but with dark barring, sometimes obscure paler barring on belly, male with orange-red patch from crown centre to nape, female with red restricted to hindcrown or, rarely, absent. Race *gravirostris* differs from nominate only in significantly longer tail and longer bill. **VOICE.** Call "peek-kit" or "pee-dink", often trisyllabic; also "kit-kit-kit-kit" varying in length. Both sexes drum, long rolls; rhythmic tapping at nest-hole.

**Habitat.** Tall, open mixed coniferous forest in mountains, particularly with ponderosa pine (*Pinus ponderosa*), sugar pine (*P. lambertiana*), lodgepole pine (*P. contorta*), white fir (*Abies concolor*), incense cedar (*Calocedrus decurrens*), also Douglas fir (*Pseudotsuga menziesii*); habitats of S race *gravirostris* characterized by similar conifer species, also by presence of Coulter pine (*P. coulteri*) and Jeffrey Pine (*P. jeffreyi*). Mainly below 700 m in far N; at 850-1600 m in Washington and Oregon; 1000-2750 m in California (Sierra Nevada), exceptionally to 3200 m, *gravirostris* mainly at 1500-2300 m.

**Food and Feeding.** Animal food mostly insects and their larvae, especially ants, beetles, also scale insects (Homoptera); pine seeds regularly taken from cones, and pine sap also taken. Accepts suet at feeders. Mostly singly or in pairs. Forages mainly on lower trunk of large conifers, also on large branches and among needle clusters; clings acrobatically to cones; also descends to ground. Searches non-coniferous trees less frequently. Favoured stratum shifts moderately with season, foraging in crown becoming more frequent in early summer. Sexual differences in foraging most pronounced in S of range: females feed more on trunks, males more on cones, particularly the huge ones of Coulter pine. Foraging techniques include removal of bark, probing and pecking; hammers rarely. Occasionally sallies after aerial insects.

**Breeding.** May-Jul; from Apr in S. Flutter-aerial display by male during courtship. Nest excavated by both partners, duration 3-4 weeks, mostly at height of 2-4 m (rarely even up to 32 m), in snag, sloping log, stump, or live tree with soft centre caused by heart-rot, and majority of sites in conifer; sometimes in fence post; hole diameter averages c. 4-6 cm, cavity depth 20-25 cm. Clutch usually 4-5 eggs, but 3-7 recorded; incubation by both sexes, period 14 days; both parents brood and feed chicks, remove faecal material, nestling period c. 26 days; fledglings divided between parents, accompanied for several weeks. In Oregon, 83-87.5% of nests produced at least 1 fledgling.

**Movements.** Some downslope movement and wandering after breeding season. Recorded outside normal range on several occasions, including rare small-scale influxes on Pacific coast, e.g. 19 individuals in coastal California in 1987/88 winter. Vagrants recorded E to NW Wyoming.

**Status and Conservation.** Not globally threatened. Uncommon to rare in N of range; fairly common to common elsewhere. Occurs in low densities: estimates include 0.5 birds/40.5 ha in managed mixed coniferous forest and 1 bird/40.5 ha in old-growth coniferous in NE Oregon; 0.18-1.06 birds/40 ha in C & SC Oregon; somewhat higher in California, average 2.3 birds/40 ha in Sierra Nevada during 1948 to 1978, with later estimates ranging from maximum of 1.2 birds/40 ha (early 1980's) to locally 3.0-5.5 birds/40 ha (W Sierra Nevada, 1988-1992). Home range in C Oregon 67-163 ha in continuous habitat and 57-445 ha in fragmented habitat; respective figures in SC Oregon 172-324 ha and 171-704 ha. Total population seems unlikely to be very high. Probably stable or increasing generally since late 1960's; declines reported locally owing to degradation or fragmentation of habitat, as in Oregon and Idaho; loss of large trees of ponderosa pine considered greatest threat to species in Oregon. Relatively tolerant of forest disturbance so long as suitable snags and stumps remain; also tolerates close short-term presence of humans.

**Bibliography.** Anon. PLATE 36

## PLATE 36

## Family PICIDAE (WOODPECKERS) SPECIES ACCOUNTS

### 119. Eurasian Three-toed Woodpecker

#### *Picoides tridactylus*

**French:** Pic tridactyle **German:** Dreizehenspecht **Spanish:** Pico Tridáctilo Euroasiático  
**Other common names:** Three-toed Woodpecker (with *P. dorsalis*)

**Taxonomy.** *Picus tridactylus* Linnaeus, 1758, Sweden.

Forms a superspecies with *P. dorsalis*, and commonly treated as conspecific; genetic evidence, however, coupled with geographical isolation and differences in plumage, indicate that the two are probably better considered separate species. Closely related also to *P. arcticus*, but links with other American congeners apparently not strong. Currently accepted races designated according to coloration, but variation is clinal, birds becoming darker and larger from N to S; revision based on genetic and biogeographical grounds required. Birds from Sakhalin, described as race *sakhalinensis*, appear indistinguishable from nominate; named races *tianschanicus* (Tien Shan), *kurodai* (Korea) and *inouyei* (EC Hokkaido) barely differ from European *alpinus*, thus regarded as better merged with that taxon. Five subspecies recognized.

#### **Subspecies and Distribution.**

*P. t. tridactylus* (Linnaeus, 1758) - N Europe E across S taiga to Altai Mts, N Mongolia, Manchuria, Ussuriland and Sakhalin.

*P. t. crissoleucus* (Reichenbach, 1854) - N taiga from Urals E to Sea of Okhotsk.

*P. t. albidior* Stejneger, 1885 - Kamchatka.

*P. t. alpinus* C. L. Brehm, 1831 - mountains of C, S & SE Europe, Tien Shan, NE Korea and N Japan (Hokkaido).

*P. t. funebris* J. Verreaux, 1870 - SW China to Tibet.

**Descriptive notes.** 20-24 cm; male 65-74 g, female 54-66 g (*tridactylus*), 46-76 g (other races). Male has long nasal tufts mixed black and white, black forehead mottled whitish, brass-yellow or pale lemon-yellow central forecrown usually with some black and white feather bases showing through; glossy black crown sides, hindcrown and band down central hindneck, crown usually with some white streaks; white supercilium from rear of eye broadening backwards, extending as band down rear neck side to meet white of mantle; glossy black from in front of and just below eye, through ear-coverts and down neck side, bordered by broad white cheekband; deep black malar stripe, obscured by white tips near bill, extending back to broad area of black on neck side that continues irregularly down to upper breast side; white chin and throat; white central mantle, inner-

most scapulars, back and rump, a few dull black spots or bars at margins, dull brownish-black mantle side, remaining scapulars and uppertail-coverts; dull brownish-black wings, outer coverts occasionally with white dots, flight-feathers with variably sized white spots largest on inner webs, including those of tertials, forming prominent barred pattern; uppertail black, tips of outer 3 feather pairs with increasing amount of black-barred white; white below, faintly tinged cream-buff in fresh plumage, breast side streaked black, flanks and undertail-coverts variably barred; longish bill straight, chisel-tipped, very broad across nostrils, slaty-

grey, darker tip, paler base of lower mandible; iris deep red or brown-red; legs slate-grey, only 3 toes. Differs from *P. dorsalis* mainly in larger size, more white on forehead, broader white head stripes, black bars in outer tail. Female has forehead and crown black with variable amount of white spots and streaks. Juvenile duller, browner, than adult, with white of back less extensive and sometimes barred, underparts duller and buffier with heavier but diffuse markings, eyes paler, male with dull yellow forecrown patch smaller than on adult, patch probably reduced or sometimes absent on female. Races differ mostly in amount of white in plumage. E ones also on average slightly larger and longer-billed; *crissoleucus* has plumage more fluffy than nominate, more white on head, back and flight-feathers, less black in outer tail, very few or no markings below; *albidior* is even whiter, with pure white outer tail and underparts, much white in wings, including spots on coverts; *alpinus* is darker overall, with white of back narrower and barred or spotted black, dark underside pale-barred with narrow central white band, outer tail more broadly barred black, juvenile mostly dark above and below with pale restricted to throat, spots on mantle and mottling on underparts; *funebris* is considerably darker, black above with narrow area of white or a few pale bars, thin white bars on outer tail and flight-feathers, pale buffish throat contrasting with finely pale-barred black underparts. Voice, Single "kip", in series when alarmed; short, "kri-kri-kri-kri-kri". Both sexes drum, rolls slightly accelerating at very end.

**Habitat.** Mature boreal and montane mixed conifer forests. Spruce (*Picea*) and fir (*Abies*) forest typical habitat in N Europe; in E European natural forest, territories are in wettest parts of ash-alder (*Fraxinus-Alnus*), coniferous and oak-hornbeam (*Quercus-Carpinus*) stands; primarily in taiga of

larch (*Larix*) in Siberia. Forest with a good proportion of insect-infested dead trees and fallen timber, and often dense and shady, are favoured. Outside breeding season, also in more open areas or brush. Will concentrate locally in windfall areas, also takes advantage of forest areas damaged by insect plagues or pollution. Mainly lowlands at higher latitudes; from 650 m and to over 1900 m in European Alps; at 3300-4000 m in SE Tibet.

**Food and Feeding.** Larvae and pupae of beetles living beneath bark form bulk of diet, and also important as nestling food; other insect larvae (hymenopterans) and imagines also taken, also spiders. Insects prone to occur in heavy infestations, e.g. *Polygraphus* and *Ips*, particularly frequent items. Apart from sap, vegetable matter (e.g. berries, spruce seeds) taken only occasionally. Forages singly; local concentrations in areas of food abundance, especially in areas of insect plagues. Prefers trunks of dead trees and stubs, foraging mostly at heights of 1-3 m, occasionally on ground. On average, males forage slightly lower than females, mainly on trunks, and prefer large trees; females forage slightly higher up and have a greater niche breadth, also using relatively thin trees and branches, and more frequently live trees (in summer). Both sexes forage lower in winter. Pecking, hammering and, especially, stripping-off of bark are predominant foraging techniques; glean-ing and probing less common. Conspicuous sap wells drilled into a wide range of tree species, mainly conifers, locally lime (*Tilia*), trees becoming covered with sap holes from base of trunk up into crown; this habit seems to be particularly common in subalpine zone.

**Breeding.** Laying from mid-May, up to 2 weeks earlier in S Europe. Courtship from second half of Mar; flutter-aerial display, bill-pointing, head-swinging with crest erect. Nest-hole excavated in dead tree, or in dead section of live tree with heart-rot, with spruce and other conifers preferred, hole diameter averages 4-7 cm, cavity depth 30-5 cm; usually a new nest made each year. Clutch 3 or 4 eggs in Alps, 3-6 (rarely 7) with mean 4-1 in Scandinavia; both sexes share all nest duties; incubation period 11-14 days, nestling period 22-26 days; fledglings accompanied by parents for up to c. 1 month. Average young produced per nest 1-7 in Switzerland; dormice (*Eliomys*) possibly significant nest predators. First breeding probably at 1 year.

**Movements.** Mountain populations (Alps, Tien Shan, Altai) sedentary; N Eurasian populations perform eruptive migrations at long intervals. In Scandinavia, most juveniles move out of nesting area and appear far outside breeding areas; Siberian populations (*crissolaeus*) regularly migrate greater distances.

**Status and Conservation.** Not globally threatened. Fairly common, locally common, but numbers vary annually; rather scarce in many parts of range. Estimated W European population in 1990's c. 51,370-65,340 pairs, with further 10,000-100,000 pairs in European part of Russia, combined total probably c. 90,000 pairs; largest known concentrations in Finland (15,000-20,000) and Belarus (9000-14,000), with 10,000-25,000 in Scandinavia. Densities vary depending on habitat quality; in Finland, 10 pairs/km<sup>2</sup> in partially burned old-growth forest but 0-0.3-1.2 pairs in other habitats; lower densities in S European mountains, e.g. 1 pair/42-200 ha (mean 108 ha) in Switzerland, and all pairs requiring home range of at least 100 ha. Has expanded since 1980's in C Europe, but declines also noted in some areas (e.g. Czech Republic); evidence of reduction in numbers in N Europe. No data on Asian populations, but said to be locally common in China; occurs in Jiuzhaigou Reserve, in China. Conservation requires preservation of sufficient areas of habitat with plenty of old and dead or dying trees.

**Bibliography.** Alekseev & Martynov (1986), Ali & Ripley (1983), Amcoff & Eriksson (1996), Austin & Kuroda (1953), Baciocchi & Baumgart (2001), Beaman & Madge (1998), Bergmanis & Straads (1993), Bezel (1985), Blagoslono (1968), Brazil (1991), Bürkli *et al.* (1975), Chablot & Wegmüller (1994), Cramp (1985), Delacour (1951a), Dementiev *et al.* (1966), Derleth *et al.* (2000), Desmet (1999), Échécoar & Hùe (1978), Fayt (1999), Friedmann (1997), Gardenfors (1978), Géroudet (1987), Hagemeijer & Blair (1997), Hågvar & Hågvar (1989), Hågvar *et al.* (1990), Heath & Evans (2000), Heath *et al.* (2000), Hess (1983), Hogstad (1970, 1971a, 1976a, 1976b, 1977, 1978, 1983, 1991, 1993), King (1978/79), Kropil & Korman (1991), Lanz (1950), Liberek & Baumann (1990), Linkola (1967), Lobkov (1999), MacKinnon & Phillips (2000), Mauersberger *et al.* (1982), Mikusinski (2001), Mikusinski & Angelstam (1997), Nyholm (1968), Pechacek (1992, 1994b, 1996, 1998), Pechacek & Kriřtin (1993, 1996), Rogacheva (1992), Ruge (1968, 1969a, 1971c, 1973, 1974, 1975), Ruge & Weber (1974a), Scherzinger (1972, 1982), Snow & Perrins (1998), Sollien *et al.* (1978, 1982a, 1982b, 1982c), Stradi & Hudon (1998), Stradi *et al.* (1998), Svensson *et al.* (1999), Thibault de Maisières (1940), Ullman (1995), Väisänen *et al.* (1986), Wabakken (1973), Wegmüller & Chablot (1992), Wesolowski & Tomialojc (1986), Winkler & Short (1978), Zhao Zhengjie (1995), Zink *et al.* (1995), Zusi & Marshall (1970).

## 120. American Three-toed Woodpecker

### *Picoides dorsalis*

**French:** Pic à dos rayé      **German:** Fichtenspecht      **Spanish:** Pico Tridáctilo Americano  
**Other common names:** White-backed Three-toed Woodpecker; Three-toed Woodpecker (with *P. tridactylus*)

**Taxonomy.** *Picoides dorsalis* Baird, 1858, Laramie Peak, Wyoming.

Forms a superspecies with *P. tridactylus*, and commonly treated as conspecific; genetic evidence, however, coupled with geographical isolation and differences in plumage, indicate that the two are probably better considered separate species. Closely related also to *P. arcticus*, but probably less so to other congeners. Races intergrade. Labrador birds named as separate race *labradorius*, supposedly larger and darker with more barred flanks than *bacatus*, but differences thought not to be constant or significant, and new taxon subsequently abandoned by describer. Three subspecies recognized.

#### **Subspecies and Distribution.**

*P. d. fasciatus* Baird, 1870 - NW & C Alaska E to NW Canada (E to NW & C Mackenzie and N Saskatchewan) and S to Oregon, N Idaho and W Montana.

*P. d. bacatus* Bangs, 1900 - N Manitoba and N Ontario E to N Quebec, Labrador and Newfoundland, S to Great Lakes, NE New York, N New Hampshire and NE Maine.

*P. d. dorsalis* Baird, 1858 - Rocky Mts from Montana to EC Nevada, Arizona and NW New Mexico.

**Descriptive notes.** 21-23 cm; male 50-64.5 g, female 47-59 g (*fasciatus*). Male has black forehead and fore lores mottled whitish, brass-yellow or pale lemon-yellow central forecrown usually with some black and white feather bases showing, glossy black crown sides, hindcrown and band down to central hindneck, crown usually streaked white; narrow white supercilium from rear of eye, extending as mottled line behind ear-coverts; glossy black area in front of and just below eye, through ear-coverts, black band down neck side, narrow white cheekband from lores, black malar stripe extending back to black band on neck side, continuing irregularly down to upper breast side; white chin and throat; white lower hindneck to back, brownish-black at sides, with few (variable) dark bars, black rump and uppertail-coverts; dull brownish-black wings, flight-feathers with vari-ably sized white spots forming barred pattern; uppertail black, outer feathers white towards tips and sometimes with few black bars; white underparts, barred black on sides and undertail-coverts, vari-able streaks on sides of breast and belly; longish bill straight, chisel-tipped, very broad across nostrils, grey, darker tip; iris deep red-brown; legs slate-grey, only 3 toes. Differs from *P. tridactylus* mainly in smaller size, slightly shorter bill, less white on head; from *P. arcticus* in smaller size,

sent, sometimes completely black forehead, back mostly black with few small bars or spots, female with crown all black or with just a few white speckles. Voice. Single high-pitched "kip" or "pwik"; short "klikkliklikli" rattle. Both sexes drum, rolls slow, faster at end, 2 per minute, similar to *P. arcticus* but only half as long and slower.

**Habitat.** Mature boreal and montane conifer forests; usually in denser forest than that preferred by *P. arcticus*. Spruce (*Picea*) preferred generally, but in W forests containing fir (*Abies*) or lodgepole pine (*Pinus contorta*) also occupied. Not normally found in ponderosa pine (*Pinus ponderosa*) or Douglas fir (*Pseudotsuga menziesii*), but has bred in old stands dominated by latter species and lodgepole pine in British Columbia. Often in swampy areas in E of range. Requires plenty of insect-infested dead trees and fallen timber; disturbed forest frequently occupied or visited. Also in more open areas outside the breeding season, even in urban areas during irruptions. Local concentrations form in burned sites or windfall areas, and in forest damaged by insect plagues or pollution. From 1300 m to 2700 m, locally 3350 m, in W; at 360-1250 m in E.

**Food and Feeding.** Chiefly larvae and pupae of bark beetles (Scolytidae); present species is an im-portant predator of spruce bark beetle (*Dendroctonus obesus*). Also larvae of wood-boring beetles (mainly Cerambycidae); smaller quantities of ants, larvae of hymenopterans, lepidopterans, other insects, and spiders. Minimal vegetable matter; small berries eaten rarely; some sap-drinking in spring, but this behaviour apparently less common than in *P. tridactylus*, possibly because of greater competi-tion from other Nearctic woodpeckers (*Sphyrapicus*, other *Picoides*). Forages singly or in pairs; sometimes small groups outside breeding season, mostly at local food abundances. Largely arboreal, rarely descends to ground. Prefers upper sections of trunks of dead trees and stubs. Bark-scaling is the predominant foraging technique, used especially on fire-killed trees, to expose beetles and their lar-vae; also pecks; occasionally drills sap wells, these being small and shallow.

**Breeding.** Laying from mid-May to end Jun, occasionally to early Jul, but courtship activities start in second half Mar. Nest-hole excavated by both sexes, at c. 2-10 m, mostly in dead tree, less often in section of live tree with heart-rot, spruce and other conifers preferred, but non-coniferous species (*Populus*, *Betula*, *Alnus*) also used; entrance diameter 3-8-4-5 cm, cavity depth c. 24-30 cm. Clutch 3-5 eggs, usually 4; both sexes incubate, period 11-14 days; both also brood and feed chicks, male possibly feeding more than female; fledging period undocumented, probably c. 24 days; fledglings apparently divided between parents. Success in producing at least 1 young 79-2% in Montana and Idaho. Longevity in wild at least 6 years.

**Movements.** Largely resident, but often shifts to lower altitudes or moves short distances after breeding. E populations make periodic eruptive migrations, occasionally appear S of breeding range in winter; casual records S to Nebraska, S Wisconsin and Pennsylvania; movements less marked than those of *P. arcticus*.

**Status and Conservation.** Not globally threatened. Not very common; numbers vary over years, but species can become locally common during insect outbreaks. Occurs in low densities, highest in burned or otherwise disturbed forest; c. 1 bird/4-05 ha in burned coniferous forest in SE Montana; in a Colo-rado conifer forest, 0.25 individuals/ha before burn but 1-20/ha 2 years after fire. Susceptible to habitat loss, forest degradation and fragmentation. Owing to this species' low population sizes, dependence on snags, preference for burned forest, and preference for large stands of old-growth conifer that are vulnerable to commercial cutting, there should be some concern for its survival in managed forests.

**Bibliography.** Anon. (1998b), Baldwin (1960), Bangs (1900), Beal (1895), Bent (1939), Blackford (1955), Bock & Buck (1974b), Campbell *et al.* (1990), Cyr (1995e), Cyr & Alvo (1996), Eckert, C. D. ## 121. Black-backed Woodpecker

### *Picoides arcticus*

**French:** Pic à dos noir      **German:** Schwarzrückenspecht      **Spanish:** Pico Ártico  
**Other common names:** Arctic (Three-toed) Woodpecker, Black-backed Three-toed Woodpecker

**Taxonomy.** *Picus (Apternus) arcticus* Swainson, 1832, near the sources of the Athabasca River, eastern slope of the Rockies.

Closely related to *P. tridactylus* and *P. dorsalis*. Monotypic.

**Distribution.** W & C Alaska E through C Canada (N to area W of Great Bear Lake, C Manitoba and N Ontario) to S Labrador and Newfoundland, and S, discontinuously in W, to California and W Nevada (Sierra Nevada), Wyoming, SC Saskatchewan and NE Minnesota, and in E to N Michigan, SE Ontario, New York and Nova Scotia.

**Descriptive notes.** 23-25 cm; 61-88 g. Male has white rear part of nasal tufts, yellow to golden-yellow forecrown, white lores and band running back below ear-coverts to neck side, above black submoustachial line; sometimes also a very fine pale line behind eye; white chin and throat; rest of head and entire upperparts deep blue-glossed black, rarely a few pale tips on rump feathers; black wings, coverts glossed blue and occasionally with a few small white spots, primaries and usually also secondaries with small white spots forming narrow bars; black tail with white at tip of third rectrix, white increasing in extent outwards to almost all-white outer tail; white below, lower re-gions washed greyish, black of upper mantle extending down to breast side and breaking up into bars, which become very regular on flanks and belly sides; longish bill straight, chisel-tipped, slate-grey, paler lower mandible where sometimes horn-coloured at base; iris red-brown to brown; legs dark grey or slaty, only 3 toes. Distinguished from *P. dorsalis* by bigger size, stronger bill, entirely black back, blue gloss, less white on head. Female has entire crown black. Juvenile duller and browner than adult, with more white in wing, markings below less regular and more diffuse, eyes

palmer, male with some yellow or orange-yellow on crown, female usually with a few small yellow spots or no yellow. VOICE. Very distinctive short, high-pitched double click; peculiar, long grating snarl, varying in pitch in course of delivery, changing from fast series of clicks into fast rasping snarl. Drumming rolls tend to accelerate at end.

**Habitat.** N and montane coniferous forest. Burned and windfall areas and those afflicted by outbreaks of forest pests particularly favoured. Compared with *P. dorsalis*, tends to occur in somewhat less dense habitats and not particularly tied to spruce (*Picea*), but frequents

wider range of coniferous habitats; found regularly in pine forest, mainly of jack pine (*Pinus banksiana*) and lodgepole pine (*P. contorta*), and in other conifer types, e.g. larch (*Larix*), fir (*Abies*), typically those which occur also at lower elevations. In particular, enters forest of Douglas fir (*Pseudotsuga menziesii*) and ponderosa pine (*P. ponderosa*) in areas of overlap with its sibling species. During irruptions, occurs in all kinds of wooded habitats, including parks and urban areas. Restricted to mountains in W part of range, at 1200-2400 m in S Oregon, above 1350 m in Montana, and at 1200-3100 m in California; from sea-level to 1300 m in E.

**Food and Feeding.** Largely wood-boring beetle larvae, particularly the large grubs of white-spotted sawyer (*Monochamus scutellatus*), an insect confined to burned forest, and bark-dwelling scolytids (*Pissodes*); larvae of mountain pine beetle (*Dendroctonus ponderosae*) also important component of diet. Other insects also taken, as well as spiders and centipedes (Chilopoda). Some fruits and seeds, and occasionally pieces of phloem, eaten occasionally. Mostly singly or in pairs. Forages mostly on lower sections of large-diameter trunks, to some extent also on large limbs, and on fallen timber; where available, fire-killed trees (e.g. *Pinus strobus*) strongly preferred. Generally, about half to two-thirds of trees visited are dead, and pines seem to be selected as feeding stations even when not the dominant tree species. Predominant techniques, especially in winter, are pecking, including blows which remove pieces of bark and other forms of scaling; also hammering, whereby deep excavations made into wood of dead trees; these foraging modes important throughout year, although gleaning and probing increase during breeding period. Flycatching is rare.

**Breeding.** Laying from end Apr. mostly mid-May to mid Jun. Courtship includes flutter-aerial display, raising of crown feathers. Nest excavated by both sexes, mean height above ground varying from 5 m to 11 m, in dead tree or in live one with heart-rot, often conifer but wide range of species recorded; occasionally in telephone pole, or old cavity from previous years reused; hole diameter averaged 4.4 cm and cavity depth 21 cm in one study, but can be up to 41 cm deep; exposed wood around entrance renders nest rather conspicuous. Clutch 2-6 eggs, usually 3 or 4; both sexes incubate, period not accurately documented; both parents brood and provide for young, nestling period 21-25 days; fledglings divided between parents. Of 33 nests in W Idaho, 87% produced at least 1 young; 100% success in burned forest in Wyoming; flying squirrels (*Glaucomys*) a major nest predator in some areas.

**Movements.** Resident; subject to irregular dismigration and eruptive movements, possibly caused by regional population increase due to very favourable conditions (e.g. outbreaks of spruce budworm, or following fires). Largest irruption in autumn 1974, over 460 individuals reported; such movements range S to S Ontario and New York, and occasionally recorded somewhat outside breeding range; rare visitors reach as far S as Iowa, C Illinois, W Virginia and Delaware.

**Status and Conservation.** Not globally threatened. Generally uncommon. Responds positively to fire, which increases availability of snags and foraging habitat; 0.25 birds/ha along perimeter of newly burned area in Alaska, the highest ever recorded density for this species. Significant declines noted during 1980's and 1990's in spruce-hardwood forest. Numbers can increase markedly when conditions favourable, making assessment of population sizes difficult to interpret. Main conservation focus should be on ensuring continued availability of suitable habitat; importance for this species of fire-damaged forest, and retention of snags and fallen trees, needs to be understood.

**Bibliography.** Beal (1895), Bent (1939), Blackford (1955), Boek & Boek (1974b), Bull (1981), Campbell *et al.* (1990), Crumb (1988), Cyr (1995f), Delacour (1951a), Dixon & Saab (2000), Eckstein (1983), Ellison (1992), Erskine (1959), Goggans (1989a), Goggans *et al.* (1988), Haig (1980), Harris, M.A. (1982), Hobson & Schieck (1999), Hutto (1995, 1998), Johnson (1984), Kaufman (1996), Kilham (1966a, 1983), Koenig (1986, 1987), Kreisel & Stein (1999), Lehnhausen & Murphy (1985), Lisi (1988), Mayfield (1958), McMichael & Wilcove (1977), Murphy & Lehnhausen (1998), Peck (1999), Peck & James (1983), Price *et al.* (1995), Raphael (1981), Root (1988), Saab & Dudley (1998), Setterington *et al.* (2000), Short (1974a), Small (1994), Spring (1965), Stark *et al.* (1998), Steffen (1981), Taylor (1958), Thompson *et al.* (1999), Van Tyne (1926), Villard, M.A. & Schieck (1997), Villard, P. ## Tribe COLAPTINI

Genus *VENILIORNIS* Bonaparte, 1854

## 122. Scarlet-backed Woodpecker

*Veniliornis callonotus*

French: Pic rubin

German: Scharlachrückenspecht

Spanish: Carpintero Escarlata

**Taxonomy.** *Picus callonotus* Waterhouse, 1841. Guayaquil, Ecuador.Race *major* intergrades freely with nominate in SW Ecuador, where many individuals have intermediate appearance. Two subspecies recognized.**Subspecies and Distribution.***V. c. callonotus* (Waterhouse, 1841) - SW Colombia (Nariño) and W Ecuador (S to Guayas and coastal El Oro).*V. c. major* (Berlepsch & Taczanowski, 1884) - SW Ecuador (El Oro, Loja) and NW Peru.**Descriptive notes.** c. 13 cm; 23-33 g. Male has black feathers of forehead to nape extensively tipped red, greyish-brown ear-coverts; rest of face, including very thin line below eye, white, often dirtier or even brown on rear neck side, sometimes with hint of a thin dark malar line; brownish-scarlet upperparts, usually some brown feather bases showing through (more when worn); dark brown or blackish-brown flight-feathers, redder on secondaries and tertials; uppertail blackish-brown, central feather pair blacker, outer feathers whitish-yellow and barred black; white below with very light (variable) palebuff wash, sometimes faintly vermiculated darker; fairly long, broad bill, culmen straight or slightly curved, yellowish, usually darker base and sometimes tip; iris deep brown, occasionally deep red or tinged bluish; legs greenish-grey. Female has forehead to nape wholly black, often some white feathers at rear. Juvenile is heavily mottled with olive or greyish above, buffish-white below, head pattern more diffuse, male with small red feather tips on forecrown. Race *major* differs from nominate in darker ear-coverts with pale band behind and below, on average more dark vermiculations below. VOICE. Commonest call a rattle, 1-2 seconds long; also sharp "ki-dik", sometimes in short fast series.**Habitat.** Arid scrub with scattered trees and cacti, dry deciduous forest, semi-humid forest and edges, and dense growth along watercourses; also partially cleared areas. Lowlands to 1000 m, locally to 1400 m and to 1800 m (Loja) in Ecuador; to 1500 m in Peru.**Food and Feeding.** Details of diet not recorded. Often in pairs. Forages at various levels in trees, often on smaller branches and very thin twigs.**Breeding.** No information. Season most likely Jan-Jul.**Movements.** Apparently resident.**Status and Conservation.** Not globally threatened. Reported to be very local in SW Colombia; fairly common in Ecuador and also in Peru. Occurs in Río Palenque Science Centre and Cerro Blanco Protected Reserve (Ecuador) and Tumbes National Reserve (Peru). Extension of range apparent in Ecuador since late 1970's; has spread into more humid areas, presumably as a result of deforestation.**Bibliography.** Allen (1998), Becker & López (1997), Best & Clarke (1991), Bloch *et al.* (1991), Butler (1979), Clements & Shany (2001), Hilty & Brown (1986), Kirwan & Marlow (1996), López & Gastezzi (2000), Meyer de Schauensee (1982), Olog (1968), Parker *et al.* (1982), Pople *et al.* (1997), Ridgely & Greenfield (2001), Ridgely *et al.* (1998), Rodner *et al.* (2000), Short (1985b), Stotz *et al.* (1996), Williams & Tobias (1994), Zimmer (1942).

## 123. Yellow-vented Woodpecker

*Veniliornis dignus*

French: Pic à ventre jaune

German: Gelbbauchspecht

Spanish: Carpintero Ventriamarillo

**Taxonomy.** *Chloronerpes dignus* P. L. Selater and Salvin, 1877. Antioquia, Colombia.Races rather weakly differentiated. Venezuelan birds described as race *abdominalis*, but considered inseparable from nominate. Three subspecies recognized.**Subspecies and Distribution.***V. d. dignus* (P. L. Selater & Salvin, 1877) - extreme SW Venezuela S in Andes to W slope in N Ecuador.*V. d. baezae* Chapman, 1923 - E slope of Andes in Ecuador.*V. d. valdizani* (Berlepsch & Stolzmann, 1894) - E slope of Andes in Peru.**Descriptive notes.** c. 16-17 cm; 35-40 g (*dignus*), 46 g (*valdizani*). Male has greenish-buff lower forehead, deep crimson crown to nape, rear neck sides and upper mantle, some black feather bases showing through especially on crown; blackish-olive ear-coverts bordered above by whitish stripe behind eye, below by thin white moustachial stripe; blackish chin vermiculated or spotted whitish; dark yellow-green lower mantle to back tinged bronze, lower mantle with red tips or edges, rump and uppertail-coverts barred pale and dark olive; brownish-olive wings, median and sometimes lesser coverts with pale yellow (often red-edged) spots, browner flight-feathers with small pale bars on inner webs; uppertail blackish, suffused yellow, outer 2 feather pairs barred pale; greenish-white below, becoming yellow on belly and flanks, with heavy olive-blackish bars from throat to upper flanks; underwing barred brown and yellow-white; medium-longbill straight, broad across nostrils, blackish, paler base; iris brown to red-brown; legs dark olive-grey. Female has blackish top of head. Juvenile duller and less yellow, more green, above, both sexes with some red tips on crown feathers. Races differ in bill length and in extent of barring below: *baezae* has shorter bill than nominate, dark bars below tend to be blacker and more marked on flanks; *valdizani* has longer bill than nominate, bars on rump more obscure. VOICE. Fast, weak, high-pitched nasal rattle heard infrequently.**Habitat.** Inhabits humid montane forest, especially cloudforest, and forest edge; occursrarely outside primary forest, for instance in abandoned coffee plantations. Found at lower altitudes than *V. nigriceps*. Mostly found at 1200-2700 m, rarely down to 700 m; 1400-2600 m in Ecuador; 700-2700 m in Peru.**Food and Feeding.** Diet not recorded. Usually singly or in pairs, and unobtrusive; occasionally joins mixed foraging parties. Forages in middle level of trees up to the canopy. Hammers frequently, with weak blows; spends long periods at single spot high up on tree trunk, on limbs and smaller branches.**Breeding.** Very little information suggests breeding season Mar-Aug.**Movements.** Resident.**Status and Conservation.** Not globally threatened. Uncommon in most of range; rare in Peru. Possibly quite widespread but at very low densities. Occurs in Río Nambí Nature Reserve, in Colombia. First records on W slope of Andes in N Ecuador in late 1980's may indicate possible range extension, but more likely that species had been overlooked previously.**Bibliography.** Butler (1979), Clements & Shany (2001), Davies *et al.* (1994), Donegan & Dávalos (1999), Hilty & Brown (1986), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Miller (1963), Olog (1968), Parker *et al.* (1982), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely *et al.* (1998), Salaman (1994), Salaman *et al.* (1999), Short (1985b), Stotz *et al.* (1996), Véléz & Velázquez (1998), Wetmore (1968b), Zimmer (1942).

## 124. Bar-bellied Woodpecker

*Veniliornis nigriceps*

French: Pic à ventre barré

German: Bindenbauchspecht

Spanish: Carpintero Ventribarrado

**Taxonomy.** *Picus nigriceps* d'Orbigny, 1840. Palca Grande, Ayupaya, Bolivia.Race *pectoralis* poorly differentiated. Three subspecies recognized.**Subspecies and Distribution.***V. n. equifasciatus* Chapman, 1912 - Andes from N Colombia to Ecuador.*V. n. pectoralis* (Berlepsch & Stolzmann, 1902) - Andes of Peru.*V. n. nigriceps* (d'Orbigny, 1840) - C Bolivia (Cochabamba, W Santa Cruz).**Descriptive notes.** 17-20 cm; 39-46 g (*pectoralis*). Male has red forehead to hindneck with black feather bases visible; very narrow short pale supercilium, dark olive-brown ear-coverts finely streaked pale, very thin pale moustachial line; dark olive neck side barred whitish, feathers variably tipped golden; blackish-olive chin and throat barred pale; dark olive upperparts tinged bronze, often a few dull red feather tips on mantle, with obscure paler spots or bars on rump and uppertail-coverts; olive-brown wings, feathers edged and tipped bronze-olive; uppertail blackish, outer 2 feather pairs barred pale;buffish-white below, tinged olive, with very broad dark olive bars; underwing barred brown and whitish; longish bill straight, broad across nostrils, dark grey to blue-grey, paler lower mandible; iris deep red to brown; legs grey to olive-grey. Distinguished from very similar *V. frontalis* chiefly by larger size, no white spots on forehead or upperparts, less barred tail. Female resembles male, but has forehead to nape black or with a few red feather edges, hindneck golden. Juvenile duller and greener than adult, has more barring in tail, both sexes with red crown patch, female's smaller. Race *equifasciatus* has pale and dark bars below about equal in width, underwing-coverts sometimes with very narrow pale central streaks, female with blackish crown tinged olive; *pectoralis* is very like nominate, possibly darker below with pale bars very narrow. VOICE. Occasional soft "chik", and high descending "kzzrr"; song up to c. 25 high-pitched "kec" notes, rising before dropping at end, heard infrequently.**Habitat.** Humid and wet montane forest, forest edge, stunted forest at tree-line and on mountain ridges, occasionally above tree-line in patches of *Polylepis* woodland. Prefers stands with dense undergrowth, especially of bamboo (*Chusquea*). Present at 2000-3600 m, mostly above 2600 m; locally to 4000 m in Ecuador.**Food and Feeding.** Diet not recorded. Usually seen singly, sometimes in pairs, very unobtrusive; regularly in mixed-species flocks. Forages at all levels, from canopy down to near ground. Pecks at bark, removes bark, and probes among mosses on horizontal branches.**Breeding.** Breeds Feb-Mar in Ecuador and Apr-May in Bolivia; specimens from Peru with enlarged testes in August. No other information.**Movements.** Resident; whether any altitudinal movement occurs is not recorded.**Status and Conservation.** Not globally threatened. Uncommon in Colombia; uncommon generally in Peru; rare to uncommon in Ecuador. Occurs in Podocarpus National Park (Ecuador) and fairly common in Machu Picchu Historical Sanctuary (Peru). Recorded at Abra Málaga and along Cuzco-Manu road in Peru; in Bolivia at Comarapa and Tambo, and at Sorata. A very poorly known species. Possibly overlooked owing to its unobtrusive habits, but likely to occur at very low densities in humid montane forest.

On following pages: 125. Smoky-brown Woodpecker (*Veniliornis fumigatus*); 126. Little Woodpecker (*Veniliornis passerinus*); 127. Dot-fronted Woodpecker (*Veniliornis frontalis*); 128. White-spotted Woodpecker (*Veniliornis spilogaster*); 129. Blood-coloured Woodpecker (*Veniliornis sanguineus*); 130. Red-rumped Woodpecker (*Veniliornis kirkii*); 131. Choco Woodpecker (*Veniliornis chocoensis*); 132. Golden-collared Woodpecker (*Veniliornis cassini*); 133. Red-stained Woodpecker (*Veniliornis affinis*); 134. Yellow-eared Woodpecker (*Veniliornis maculifrons*).

**Bibliography.** Bloch *et al.* (1991), Butler (1979), Clements & Shany (2001), Cresswell, Hughes *et al.* (1999), Cresswell, Mellanby *et al.* (1999), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Meyer de Schauensee (1982), Olrog (1968), Remsen, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Poulsen (1996), Remsen (1985), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Greenfield (2001), Ridgely *et al.* (1998), Short (1985b), Stotz *et al.* (1996), Véléz & Velázquez (1998), Walker (2001), Williams & Tobias (1994), Zimmer (1930, 1942).

## 125. Smoky-brown Woodpecker

### *Veniliornis fumigatus*

**French:** Pic enfumé      **German:** Rußspecht      **Spanish:** Carpintero Ahumado  
**Other common names:** Brown Woodpecker

**Taxonomy.** *Picus fumigatus* d'Orbigny, 1840, Yungas, Bolivia. Relationships uncertain; molecular-genetic analysis suggests very close relationship to *Picoides villosus*, perhaps to extent that the two could justifiably be treated as congeneric; further study needed. Races intergrade to some extent; birds from SW Ecuador may be intermediate between nominate and race *obscuratus*. N Colombian (Santa Marta) birds previously separated as race *exsul*, those of NE Venezuelan mountains as *tectricialis*, and those of C Colombia and Ecuador as *aureus*, but all appear insufficiently different to warrant recognition. Five subspecies currently recognized.

**Subspecies and Distribution.**

*V. f. oleagineus* (Reichenbach, 1854) - E Mexico.  
*V. f. sanguinolentus* (P. L. Sclater, 1859) - C & S Mexico to W Panama.  
*V. f. reichenbachi* (Cabanis & Heine, 1863) - N & NE Venezuela.  
*V. f. fumigatus* (d'Orbigny, 1840) - E Panama and Colombia S through Ecuador and E Peru to W Bolivia and NW Argentina (Jujuy).  
*V. f. obscuratus* Chapman, 1927 - SW Ecuador (El Oro and W Loja) to NW Peru (Huancabamba and bend of R Marañón).

**Descriptive notes.** 18 cm; 31-40 g (*sanguinolentus*), 36-42 g (*oleagineus*), 35-50 g (*reichenbachi*). Male has red forehead to nape, forehead and crown with dark feather bases showing; rest of head and neck olive-brown, ear-coverts paler, whitish lores and thin line above eye, dark malar stripe with very thin whitish line above; brown to olive-brown upperparts, mantle tinged red or with some golden to orange feather edges when fresh, rump and uppertail-coverts duller brown; dark brown wings, coverts tinged greenish and often with some red edges, flight-feathers barred pale on inner webs; uppertail blackish-brown,

outer feathers paler brown; olive-brown below, uniform or with paler lower region, latter occasionally with faint darker bars; underwing barred whitish and brown; rather long bill straight, broad across nostrils, blackish, paler lower mandible; iris deep brown to red-brown; legs greyish. Female has forehead to nape olive-tinged dark brown, occasionally with a few white speckles. Juvenile similar to adult but duller, more sooty-brown, lacking bright tinges above, with some white bars on inner webs of secondaries, male with dull red crown patch sometimes reaching to nape, on female normally restricted to forecrown. Races differ mainly in plumage tone and wing length: *oleagineus* is longer-winged than most, has much white around eyes; *sanguinolentus* is smaller, shorter-winged, richer brown than previous, has pale ear-coverts, no obvious whitish around eye; *reichenbachi* resembles previous, but slightly longer-winged, and duller brown; *obscuratus* has longest wing, is similar to previous but with darker, more grey-brown, plumage. Voice. Short "wick", "chuk", "pwik" or "quip", softer and more slurred than similar note of *Picoides villosus*; rattle fast, high-pitched and piping "keer-keer-keer-keer" or hard, rolling, gravelly "zur-zur-zur-zur", at higher intensity as "tchk, tchk zr-r-r-uh kuh-kuh-kuh-kuh"; squeaky, sucking "wick-a wick-a" or "tsewink tsewink" in interactions. Drums in very rapid, protracted tattoos.

**Habitat.** Humid and wet forest, cloudforest, dry montane woodland with *Eugenia*, alder (*Alnus*) woodland, occasionally above tree-line in patches of *Polylepis* growth. Oak (*Quercus*) forest in Mexico. In lowlands, forest edge and clearings, also along wooded streams, in shady and tall second growth, in thickets, lighter woodland and woodland borders with dense understorey, and coffee plantations. Occurs from almost sea-level up to 1500 m in Mexico; in lowlands up to 750 m, locally to 1850 m, through Central America; at 800-2700 m in Venezuela; mostly 1200-2800 m in Colombia and Peru, occasionally as low as 600 m, or higher, up to at least 4000 m in Peru (Cordillera Blanca); 600-2400 m in Ecuador, mostly at 1000-1800 m, but recorded to 2700 m; 1200-2500 m in Argentina.

**Food and Feeding.** Small wood-boring beetles and their larvae comprise bulk of diet, occasionally supplemented with fruits. In pairs throughout year, but often forages singly, or in family groups of 4-6 birds after breeding; often joins mixed-species flocks. Forages high in broken canopy or lower at edges and in undergrowth; often in vine tangles or on slender branches and among foliage, mostly at middle and low levels. Also visits isolated trees. Moves along branches with many sideward lunges. Pecks and hammers industriously on variety of substrates, from thin stems to large branches and vines. Probing infrequent; gleaming seems rarely to be used.

**Breeding.** Feb-Jun in Central America, Feb-Mar in N Venezuela, and Oct-Apr in Colombia. Nest-hole dug by both sexes, 1-5-8 m up in dead limb or tree trunk or in fence post. Clutch 4 eggs; no data on incubation and fledging periods.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common in Central America, perhaps somewhat less common farther S; uncommon to fairly common in Ecuador, fairly common in Peru, locally frequent in Argentina. Occurs in numerous protected areas, including Braulio Carrillo National Park and Monteverde Biological Reserve (Costa Rica), Henri Pittier National Park (Venezuela), Río Nambí Nature Reserve (Colombia), Protected Forest of Alto Mayo (Peru) and Calilegua National Park (Argentina). Probably reasonably secure.

**Bibliography.** Best & Clarke (1991), Binford (1989), Blendinger (1998), Bloch *et al.* (1991), Canevari *et al.* (1991), Clements & Shany (2001), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Friedmann *et al.* (1957), Hernández *et al.* (1995), Hilty (1995), Hilty & Brown (1986), Howell & Webb (1995), Koepecke (1961), Mazar Barnett *et al.* (1998), Meyer de Schauensee & Phelps (1978), Miller (1963), Monroe (1968), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), de la Peña (1994), Remsen *et al.* (1986), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Rojas *et al.* (2001), Salaman (1994), Schaldach (1963), Short (1985b), Slud (1964), Stiles (1985), Stotz *et al.* (1996), Thurber *et al.* (1987), Wetmore (1968a), Zimmer (1930, 1942).

## 126. Little Woodpecker

### *Veniliornis passerinus*

**French:** Pic passerin      **German:** Sperlingsspecht      **Spanish:** Carpintero Chico

**Taxonomy.** *Picus passerinus* Linnaeus, 1766, Dominica; error = Cayenne.

Forms a superspecies with *V. frontalis*; the two sometimes hybridize, and have occasionally been considered conspecific. Races tend to intergrade. Birds from extreme W French Guiana described as race *saturatus* and those from E Brazil (N Goiás, W Bahia) as *transfluvialis*, but appear to be no more than intergrades. Nine subspecies recognized.

**Subspecies and Distribution.**

*V. p. modestus* J. T. Zimmer, 1942 - NE Venezuela.  
*V. p. fidelis* (Hargitt, 1889) - W Venezuela to E Colombia.  
*V. p. passerinus* (Linnaeus, 1766) - the Guianas and NE Brazil.  
*V. p. diversus* J. T. Zimmer, 1942 - N Brazil.  
*V. p. agilis* (Cabanis & Heine, 1863) - E Ecuador E to W Brazil and S to N Bolivia.  
*V. p. insignis* J. T. Zimmer, 1942 - WC Brazil.  
*V. p. tapajozensis* Gyldenstolpe, 1941 - C Brazil.  
*V. p. taenionotus* (Reichenbach, 1854) - E Brazil.  
*V. p. olivinus* (Natterer & Malherbe, 1845) - S Bolivia, S Brazil, Paraguay and NW & NE Argentina.

**Descriptive notes.** c. 14-15 cm; 24-37 g. Male has greyish forehead, red forecrown to hindneck with dark feather bases showing; rest of head dark brownish-olive, neck sides with paler feather tips, chin and throat barred pale; bronzy olive-green above sometimes with a few red feather tips, with variable obscure paler barring very indistinct, most evident on rump, median wing-coverts usually with small subterminal spots; brown flight-feathers edged green, broadly on secondaries and tertials, narrow whitish bars on inner webs of primaries and secondaries; uppertail dark brown, outer feathers usually with some thin pale bars; dark

olive underparts entirely barred buffish-white, underwing barred olive-brown and pale; fairly long bill straight, broad across nostrils, blackish, paler lower mandible; iris deep brown; legs dark grey. Distinguished from *V. frontalis* by smaller size, lack of pale facial stripes, lack of obvious spots and bars above, less barred tail. Female lacks red on head, has forehead to nape greyish olive-brown, usually with indistinct pale spots. Juvenile resembles adult but duller, less bronzy, with bars below less regular, eyes paler, both sexes with dull red crown patch, smaller on female. Races differ mainly in presence of facial stripes, extent of red on male's head, tone of upperparts and amount of spotting in wing-coverts, nature of barring below, and size: *modestus* has fairly prominent whitish moustachial line, obvious pale wing-coverts spots, grey-brown underparts with breast barring irregular; *fidelis* has pale supercilium, much more marked whitish moustachial line, larger wing-covert spots, breastbars broken or scallop-shaped, tail usually unbarred; *diversus* has only faint indication of facial stripes or none at all, wing-coverts sometimes with very narrow pale shaft streaks, bars below broad, male with red only from central crown to hindneck; *agilis* has well-developed supercilium and moustachial stripes; *insignis* is smallest, has no pale facial stripes, no wing-covert spots, pale bars below broad, red on male as previous; *tapajozensis* is tinged yellower above with some red spots, red of male's head extending to forecrown; *taenionotus* is even yellower above, often with scattered red tips and stronger hint of barring, has larger wing-covert spots, pale bars below noticeably broad, red of male's head extending to forehead; *olivinus* is largest, usually has short pale supercilium (often absent), thin whitish moustachial (often partly lacking), male with red restricted to hindcrown and nape. Voice. High-pitched "ki, ki, ki, ki" or "wi-wi-wi-wi-wi-wi", apparently as long-distance call; also "wicka" or series of "wik-wik-wik" in encounters. Drums.

**Habitat.** Rather versatile, generally preferring edges and clearings, and second growth. Occurs at edges of humid forest, including cloudforest, *várzea* forest, riparian forest, also gallery forest with bamboo bordering swampy lagoons and rivers; also deciduous woodland, mangroves, second growth, transitional forest, densely wooded savanna, shrub-forest (*caatinga*), also lightly wooded habitats, including savanna with scattered trees. Occasionally visits gardens. To 850 m in N Venezuela and 1200 m in Colombia; to 1300 m but mostly below 700 m in Ecuador, to 900 m in Peru and to 400 m farther S.

**Food and Feeding.** Ants, termites (Isoptera), beetles and their larvae, and various other insects. Found singly, in pairs or in small groups; joins mixed-species flocks. Forages from low in undergrowth, preferentially on bamboo, to upper levels in trees; often in semi-open sites. Techniques include vigorous pecking and hammering on bark, branches and limbs, around bamboo nodes, and on saplings; small holes drilled by hammering.

**Breeding.** Sept-Dec in French Guiana and Oct-Mar in Argentina; copulation observed in Feb in Colombia. Displays include wing-spreading, head-swinging, tail-spreading. Nest excavated possibly by male only, at 5-13 m in stub, palm or bamboo. Details of clutch size and incubation and fledging periods not documented; observations suggest that possibly male alone tends brood.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common in Ecuador; fairly common in Peru. Appears generally to be not uncommon. Occurs in Serra do Cipó and Chapada dos Guimarães National Parks (Brazil) and Podocarpus National Park (Ecuador). An adaptable species, able to exploit a variety of wooded habitats.

**Bibliography.** Allen (1995), Brace *et al.* (1997), Canevari *et al.* (1991), Clements & Shany (2001), Contreras *et al.* (1990), Ferreira de Vasconcelos & Melo-Júnior (2001), Guix *et al.* (1999), Hayes (1995), Hilty & Brown (1986), Lima & Aleixo (2000), Maldonado-Coelho & Marini (2000), Marini (2001), Marini *et al.* (1997), Melo-Júnior (2001a), Meyer de Schauensee & Phelps (1978), Munn (1985), Oniki & Willis (1999), Parker *et al.* (1982), de la Peña (1994), Pinto & Camargo (1961), Piratelli *et al.* (2000), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Robinson (1997), Robinson & Terborgh (1997), Short (1975), Sick (1993), da Silva *et al.* (1997), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Straube & Bornschein (1995), Terborgh *et al.* (1984), Thiollay & Jullien (1998), Tostain *et al.* (1992), Tubelis & Tomás (1999), Wetmore (1926), Zimmer (1942).

## 127. Dot-fronted Woodpecker

### *Veniliornis frontalis*

**French:** Pic étoilé      **German:** Perlstirnspecht      **Spanish:** Carpintero de las Yungas

**Taxonomy.** *Cloronerpes* [sic] (*Campias*) *frontalis* Cabanis, 1883, Tucumán, Argentina. Forms a superspecies with *V. passerinus*; the two sometimes hybridize, and have occasionally been considered conspecific. Monotypic.

**Distribution.** Andes from Bolivia (Cochabamba, W Santa Cruz) S to NW Argentina (S to Tucumán).

**Descriptive notes.** c. 16 cm; 30-40 g. Male has olive to grey-brown forehead heavily spotted with white, red forecrown to nape with extensive dark grey feather bases showing through, yellowish-olive hindneck; long thin white supercilium, thin white line from lores, one or both often partly obscured by darker spots; rest of head olive-brown, ear-coverts streaked buffish, neck side and chin barred pale; yellowish-olive upperparts barred and streaked pale and with golden feather tips (markings much less obvious in worn plumage), median wing-coverts and outer scapulars with pale wedge-shaped spots, greater coverts with narrow pale central streaks; brown flight-feathers broadly edged yellow-green, narrowly pale-barred on inner webs; uppertail dark brown with thin whitish bars (bars less distinct on central feathers), all suffused yellow; olive-grey underparts all narrowly barred whitish, underwing barred dusky and pale; fairly long bill straight, broad across nostrils, slate-grey to blackish, paler lower mandible; iris dark brown; legs dark grey. Differs from *V. passerinus* in larger size, facial stripes (also present in some races of latter), stronger markings above, barred tail. Female has crown to nape olive-brown with white spots. Juvenile duller and greyer than adult, both sexes with red crown patch, smaller on female. **VOICE.** Similar to that of *V. spilogaster*; makes series of 8-10 "juic!" or "jic!" calls, or a rather harsh "wik!". Also utters similar cries as isolated individual calls.

**Habitat.** Dry montane woodland and transitional and humid forest of Andean slopes; to 2000 m, generally lower. **Food and Feeding.** Diet not described. Often forages at low levels, near ground, on trunks and smaller branches. **Breeding.** Very few data. Active nest in mid-Nov in Argentina; juveniles recorded in Sept and Oct. Single known nest c. 8 m above ground in cavity in dead tree; male apparently incubating. No other information. **Movements.** Some downslope movements occur outside breeding season.

**Status and Conservation.** Not globally threatened. Generally rather uncommon. In Argentina, occurs in El Rey National Park and fairly common in Calilegua National Park. Very poorly known species; research required on its ecology and reproduction. **Bibliography.** Babarskas *et al.* (1995), Blake & Rougès (1997), Canevari *et al.* (1991), Chebez *et al.* (1999), Contreras (1983), Di Giacomo & López (2000), Fjeldså & Mayer (1996), Malizia (2001), Malizia *et al.* (1998), Mazar Barnett & Pearman (2001), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Nates *et al.* (2000), Olog (1968), de la Peña (1994), Rensen & Traylor (1989), Short (1985b), Stotz *et al.* (1996), Wetmore (1926).

128. White-spotted Woodpecker  
*Veniliornis spilogaster*

**French:** Pic aspergé      **German:** Perlbauchspecht      **Spanish:** Carpintero Manchado

**Taxonomy.** *Picus Spilogaster* Wagler, 1827, Brazil and Paraguay. Monotypic. **Distribution.** SE Brazil (S from Minas Gerais) S to adjacent SE Paraguay, NE Argentina (Misiones, E Corrientes) and Uruguay.

**Descriptive notes.** 16-19.5 cm; 35-45 g. Distinctive small woodpecker. Male has buffy to olive lower forehead, blackish-brown crown very narrowly streaked dark red when fresh (plainer in worn plumage), olive-green hindneck; brownish ear-coverts patterned with white, bordered above by thin white supercilium, below by thin white moustachial stripe; pale chin and side of neck striped dark olive-brown; olive-green upperparts with pale yellowish to white feather edges forming bars, sometimes becoming spots on rump, dark olive wing-coverts tipped whitish, dark brown flight-feathers barred whitish; uppertail dark

brown, narrowly barred off-white; dark olive underparts heavily streaked yellowish-white on throat, barred or spotted on breast, heavily barred in lower regions, underwing barred brown and white; rather short to longish bill straight, broad across nostrils, blackish-grey, paler base, often yellowish base of lower mandible; iris deep chestnut-brown; legs olive or olive-grey. Female has noticeably shorter bill than male, crown olive-brown and finely spotted white. Juvenile much as adult, but bars above less obvious and less regular. **VOICE.** Single "pic" notes in mild alarm; also great variety of other distinctive calls, e.g. sharp "cheekit" and "ti-rra-rra", "reh-reh-reh-reh" and similar, or "cheekit ch che che che che"; variable high-pitched, almost whistled chittering by nestlings. Gentle tapping signal in groups of 2-4, with pauses and single taps, also described.

**Habitat.** Various types of forest and woodland, from humid lowland forest, riverine forest and isolated forest patches to open and very open woodland and open parkland with low and spiny trees. **Food and Feeding.** Beetle larvae and other insects; berries also taken. Observed foraging on tree trunks, saplings and fence posts; pecks, and hammers vigorously to excavate bark. Also plucks berries.

**Breeding.** Apparently breeds in Aug-Oct, or to Nov. Nest-holes excavated low down, once at 2-2 m, in stub, the chamber occupying most of the heartwood. No information on clutch size or on incubation and fledging periods.

**Movements.** Resident. **Status and Conservation.** Not globally threatened. Common; locally very common. Occurs in Itatiaia National Park and Aparados da Serra National Park (Brazil) Ybicuí National Park (Paraguay) and Iguazú National Park (Argentina). Fairly adaptable, able to use a variety of wooded habitats.

**Bibliography.** Aleixo & Galetti (1997), dos Anjos (2001), dos Anjos & Schuchmann (1997), dos Anjos *et al.* (1997), Belton (1984), Benecke & Kindel (1999), Brooks *et al.* (1993), Buzzetti (2000), Canevari *et al.* (1991), Capper *et al.* (2000), Figueiredo & Lo (2000), Figueiredo *et al.* (2000), Goerck (1999), Guix, Martín & Mañosa (1999), Guix, Tabáñez *et al.* (1992), Hayes (1995), Hayes & Scharf (1995a), Lowen *et al.* (1995), Machado &

Rodrigues (2000), Madroño, Clay, Robbins *et al.* (1997), Madroño, Robbins & Zyskowski (1997), Meyer de Schauensee (1982), Olog (1968), Parker & Goerck (1997), de la Peña (1994, 1997), do Rosário (1996), Short (1985b), Sick (1993), Soares & dos Anjos (1999), Stotz *et al.* (1996), Tobias *et al.* (1993), Wetmore (1926).

129. Blood-coloured Woodpecker  
*Veniliornis sanguineus*

**French:** Pic rougeâtre      **German:** Blutrückenspecht      **Spanish:** Carpintero Sanguíneo

**Taxonomy.** *Picus sanguineus* A. A. H. Lichtenstein, 1793, Guyana. Monotypic. **Distribution.** Coastal lowlands of the Guianas.

**Descriptive notes.** c. 13 cm; 23-30 g. Male has brown forehead faintly spotted white, crimson-red crown to hindneck with brown feather bases and centres usually fairly visible; brown superciliary area, ear-coverts and neck side, ear-coverts usually very finely streaked whitish; chin, throat and malar region barred dark and pale brown; upperparts dark crimson-red with extensive greenish-brown feather bases, dark brown wing-coverts broadly edged and tipped crimson, medians with a few tiny white spots; dark brown flight-feathers, primaries edged greenish-brown, secondaries and tertiaries broadly edged crimson; uppertail dark brown;

dark brownish underparts barred off-white, bars broader on belly, underwing entirely barred brown and whitish; in worn plumage red areas duller and much browner, underparts even more boldly barred; relatively long bill straight, broad across nostrils, dark grey, paler tip; iris dark red-brown; legs blackish. Female as male, but has crown brown with fine white feather tips. Juvenile as adult, but duller and browner, feathering looser, usually larger pale wing-covert spots. **VOICE.** Common call single "keek" notes; fast series of c. 16 "wih" notes also given; nestlings produce rattling noise. Both sexes drum.

**Habitat.** Mangroves, swampy forest, also coffee plantations; lowlands. **Food and Feeding.** Ants, beetles (Cerambycidae), caterpillars. Usually singly or in pairs. Forages in trees and shrubs of various kinds.

**Breeding.** Recorded in Feb-Mar and May-Nov in Surinam. Hole excavated by both sexes, working for up to 2 months, low down (e.g. 1-4 m) in stump or larger branch. Partners may copulate before entering joint roost. Clutch 1 or 2 eggs, sometimes 3; both parents incubate; nestlings apparently fed with single food items, by both sexes, male accounting for slightly larger share; incubation and fledging periods not documented; pair-members roost together, and may share roost with another individual, presumably young of previous brood, until next brood initiated.

**Movements.** Resident. **Status and Conservation.** Not globally threatened. Reasonably common. Fairly widespread in its range, but restricted to lowlands of the Guianas. No information on numbers, but probably secure; loss of habitat could become a threat, although no indication of this occurring in the short term. **Bibliography.** Haverschmidt (1953), Haverschmidt & Mees (1994), Meyer de Schauensee (1982), Olog (1968), Rodner *et al.* (2000), Short (1985b), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Wheatley (1994).

130. Red-rumped Woodpecker  
*Veniliornis kirkii*

**French:** Pic à croupion rouge      **German:** Blutbürzelspecht      **Spanish:** Carpintero Culirrojo  
**Other common names:** Kirk's Woodpecker

**Taxonomy.** *Picus (Chloropicus) Kirkii* Malherbe, 1845, Tobago. Forms a superspecies with *V. chocoensis*, *V. cassini*, *V. affinis* and *V. maculifrons*. Five subspecies recognized.

**Subspecies and Distribution.** *V. k. neglectus* Bangs, 1901 - SW Costa Rica and W Panama, including Coiba I. *V. k. cecilia* (Malherbe, 1849) - E Panama and W Colombia S to W Ecuador and extreme NW Peru (Pacific slope S to Lambayeque). *V. k. continentalis* Hellmayr, 1906 - W & N Venezuela. *V. k. kirkii* (Malherbe, 1845) - Trinidad and Tobago and NE Venezuela. *V. k. monticola* Hellmayr, 1918 - Mt Roraima and Cerro Uei-tepui, in SE Venezuela.

**Descriptive notes.** c. 15-16 cm; 30-42 g. Male has buffish forehead, lores and superciliary area, dusky brown or dark grey crown and nape with red feather tips, golden-yellow lower nape to upper neck side; olive-brown ear-coverts with whitish shaft streaks, whitish chin and throat barred dark olive; golden olive-brown upperparts with paler yellow shaft streaks (often obscure), sometimes some red feather edges and tips, rump and uppertail-coverts bright crimson-red; wing-coverts with pale buff wedge-shaped spots, reddish tips, mostly on medians; dark brown flight-feathers broadly edged greenish-olive, broadest on secondaries

and tertiaries, pale bars on inner webs of primaries and secondaries; uppertail dark brown, paler outer feathers barred pale buff; entirely barred olive-brown and whitish below, pale bars becoming broader in belly region, underwing barred dark brown and whitish; longish bill straight, broad across nostrils, blackish, paler lower mandible; iris dark brown to red-brown, occasionally paler orbital ring; legs dark greyish, tinged green to blue. Differs from *V. chocoensis* in red rump, less yellow nape, less patterned face, narrower pale bars below. Female lacks red on head, has crown dark brown with green tinges. Juvenile resembles adult, but both sexes have red tips on crown, female less extensively. Race *monticola* is large as nominate or larger, with heavy blackish barring below; *continentalis* is smaller, with more yellow on nape, and pale bars below broader; *cecilia* is smaller than previous, with paler chin and upper throat less patterned, wing-coverts less spotted, tail more barred; *neglectus* is usually brighter above and darker below than last, tending to lack spots on wing-coverts. **VOICE.**

Nasal "keer", decreasing in intensity, softer than similar note of *Picus simplex*, recalling kiskadee (*Pitangus*) or even *Piculus rubiginosus*; mewing "wh" or "kwee" in shorter or longer ventriloquial series of up to 16 notes, becoming louder at end, sometimes with weak throaty "yuk" or "yk" added; also repeated "kee-yik kee-yik". Drumming rapid, noisy, often prolonged.

**Habitat.** Variety of lowland and foothill habitats, from wet forest, adjacent second growth and overgrown clearings, edge of mangroves, to gallery forest, xerophytic areas, dry deciduous forest, tall open woodland, savanna, coconut (*Cocos nucifera*) plantations, cemeteries. Tends to favour rather open habitats. To 900 m in Panama; to 1000 m in W Venezuela, and to 1500-1750 m in tepuis S of R Orinoco; to c. 1200 m in Ecuador but below 300 m in NW (N Esmeraldas); to 1500 m in Peru.

**Food and Feeding.** Larvae and adults of small to medium-sized wood-boring beetles and other insects. Usually forages singly or in pairs, or in small groups; joins mixed-species flocks. Mainly in mid-levels and canopy of forest, coming lower only in adjacent second growth and clearings; visits trees at forest borders, but rarely ventures outside forest; inconspicuous. Forages on trunks to smaller branches, often among thick foliage. Pecking and hammering are frequently used techniques; hammers steadily.

**Breeding.** Dec-Feb, possibly Mar, in Panama and in Trinidad and Tobago, and Feb-Mar in N Venezuela; Jul in Ecuador; also, birds in breeding condition in Jan and Sept in Colombia and Ecuador. Nest-hole 3-8 m up in living tree or palm, even slender one, often at edge of forest; hole diameter 5 cm, cavity depth 35 cm. Clutch 2-3 eggs. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to uncommon. Uncommon to locally fairly common in Ecuador, where widespread in N lowlands; apparently no recent records from SW (Loja). Fairly common at Campo Verde (Peru). Occurs in Salamanca National Park (Colombia), Henri Pittier National Park (Venezuela), Tinalandia Natural Reserve (Ecuador) and Tumbes National Reserve (Peru). Generally inconspicuous, possibly overlooked, but presence often revealed by sound of its frequent pecking and hammering.

**Bibliography.** Anon. (1998b), Becker & López (1997), Bond *et al.* (1989), Clements & Shany (2001), Friedmann & Smith (1950), Hayes & Samad (1998), Herklots (1961), Hilty & Brown (1986), Marin & Carrión (1991), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Parker *et al.* (1982), Pople *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Robbins *et al.* (1985), Short (1985b), Slud (1964), Snow (1985), Stiles (1985), Sules & Skutch (1989), Stotz *et al.* (1996), Verea & Solórzano (1998), Verea *et al.* (2000), Wetmore (1939, 1957, 1968a).

## 131. Choco Woodpecker

### *Veniliornis chocoensis*

French: Pic du Choco

German: Chokospecht

Spanish: Carpintero del Chocó

**Taxonomy.** *Veniliornis chocoensis* Todd, 1919, Malagita, Chocó, Colombia.

Forms a superspecies with *V. kirkii*, *V. cassini*, *V. affinis* and *V. maculifrons*. Has often been treated as conspecific with second or third of those, but differs in plumage details, in size and in habitat preferences, apparently also vocally, and is separated from both by Andes chain. Monotypic.

**Distribution.** W Colombia (W Antioquia S to Nariño) and NW Ecuador (S to NW Pichincha).

**Descriptive notes.** 15-16 cm; c. 30 g. Male has buffish forehead, blackish crown with broad red feather tips, dull golden nape and upper neck side; brownish-buff lores and side of head, obscurely streaked darker at rear, often some pale tips (can appear variegated); pale buffish chin and upper throat spotted or barred darker, sometimes almost fully dark; bronzy golden-green above, mantle and scapulars often suffused red, obscure pale yellow shaft streaks, rump and uppertail-coverts barred olive and yellowish; wing-coverts with small, obscure pale yellow spots, mostly on medians; dark brown flight-feathers edged olive-yellow, barred buffish,

tertials sometimes tinged red; uppertail dark brown, barred yellowish, bars most pronounced on outer tail; underparts barred olive and whitish-buff, underwing barred pale and dark; rather short bill straight or slightly curved, broad across nostrils, dark, paler lower mandible; iris red-brown to brown; legs dark olive, tinged grey or green. Distinguished from very similar *V. cassini* by slightly brighter upperparts, dark bars below less blackish; from *V. affinis* by generally somewhat smaller size, slightly darker coloration, and less red on upperparts. Female differs from male in having crown dark olive-brown, becoming yellow-streaked on nape. Juvenile as adult but looser-plumaged, with streaked face side, both sexes with red-tipped crown feathers, on female confined mostly to central area. Voice. Details apparently not documented, but said to differ to some extent from *V. cassini* and *V. affinis*.

**Habitat.** Humid to very wet forest and forest edge in foothills, less in lowlands; recorded at up to 1000 m, mostly below 700 m. Generally prefers wetter forest than e.g. *V. affinis*.

**Food and Feeding.** Details not known; diet presumably as for *V. affinis*. Pair seen foraging with mixed-species party in primary forest in Jul and Jan in SW Colombia (Nariño).

**Breeding.** No information.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Considered Near-threatened. Restricted-range species: present in Chocó EBA. Little-known species which seems to be rare throughout its small range. Rare in Colombia; rare to uncommon and local in Ecuador, with most records in Esmeraldas. Occurs in El Pangán Reserve in Nariño, Colombia; occurs in 2 protected areas in Ecuador, in Cotacachi-Cayapas Ecological Reserve and at Bilka. Habitat loss and degradation are the most serious threats. Large-scale logging concessions, accompanied by human settlement following road construction, have already resulted in more than 40% of Chocó forest being lost or severely degraded; forest destruction continuing at accelerating rate, and most severe in altitudinal range occupied by this species. Mining activities, coca and palm cultivation and livestock grazing combine to intensify the pressure caused by intensive logging. Without appropriate measures to conserve its habitats, this species' conservation status could become Vulnerable.

**Bibliography.** Ridgely & Greenfield (2001), Ridgely *et al.* (1998), Rodner *et al.* (2000), Short (1974c), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stewie (2000b), Taylor (1995).

## 132. Golden-collared Woodpecker

### *Veniliornis cassini*

French: Pic de Cassin

German: Goldnackenspecht

Spanish: Carpintero Cebra

**Taxonomy.** *Mesopicus cassini* Malherbe, 1862, Cayenne.

Forms a superspecies with *V. kirkii*, *V. chocoensis*, *V. affinis* and *V. maculifrons*. Often considered conspecific with second, but differs in details of plumage, in habitat preferences, apparently also in voice, and is geographically isolated by Andes. Has also been regarded as possibly conspecific with third of those species, with which may overlap slightly in range; further study needed. Monotypic.

**Distribution.** E & SE Venezuela (Bolívar, Amazonas), the Guianas, and NE Brazil N of Amazon (E Roraima and lower R Negro to Amapá).

**Descriptive notes.** c. 16 cm; 24-38 g. Male has buffish lower forehead and lores, greyish-black upper forehead and crown with narrow red feather tips, larger tips on upper nape, golden-yellow lower nape to neck side and rearmost superciliary area; buffish-white ear-coverts finely streaked darker; whitish chin lightly barred or spotted dark; yellowish-green upperparts slightly bronzy, rump sometimes obscurely barred yellowish, median wing-coverts (and some greater) with pale buff subterminal spots, sometimes also basal spots; dark brown flight-feathers edged greenish, broadly on inner secondaries and tertials,

white bars on inner webs of primaries and secondaries; uppertail dark brown, obscurely barred paler, outer 2 feather pairs with clearer whitish notches; throat and underparts white to pale buffish-white, barred black to brownish-black, bars narrower in lower regions; underwing barred dark brown and white; undertail as above, but bars more obvious; rather long bill straight, fairly broad across nostrils, dark grey, paler tip and cutting edges; iris dark brown to red-brown; legs olive to dark grey or blackish, sometimes tinged blue. Differs from *V. affinis* in lack of red tones above, brighter yellow nape, more contrasting barring below. Female has crown green-tinged brown, whitish-yellow spots at rear merging with golden-yellow of nape. Juvenile greener, less yellow, above than adult, duller nape, darker face, wing-coverts more streaked, both sexes with some red on crown. Voice. Very similar to that of *V. affinis*: a series of 33-35 nasal "khir" notes, rising in frequency. Generally rather silent.

**Habitat.** Rainforest, clearings, open terrain with trees, shrubbery; lowlands to 1500 m.

**Food and Feeding.** Beetles (Cerambycidae) recorded, generally solitary, often foraging in treetops. Also joins mixed-species feeding flocks.

**Breeding.** No information available.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. A very poorly known canopy-dwelling woodpecker; possibly not uncommon, but difficult to observe. Not uncommon in Canaima National Park and Imataca Forest Reserve and El Dorado (Venezuela); observed at Manaus (Brazil). Research required to determine its ecology and breeding biology.

**Bibliography.** Cohn-Haft *et al.* (1997), Haverschmidt & Mees (1994), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Reynaud (1998), Ruschi (1979), Sargeant (1994), Short (1974c, 1985b), Sick (1993), Snyder (1966), Stotz *et al.* (1996), Thiollay & Jullien (1998), Tostain *et al.* (1992).

## 133. Red-stained Woodpecker

### *Veniliornis affinis*

French: Pic affiné

German: Blutflügelspecht

Spanish: Carpintero Teñido

**Taxonomy.** *Picus affinis* Swainson, 1821, Bahia, Brazil.

Forms a superspecies with *V. kirkii*, *V. chocoensis*, *V. cassini* and *V. maculifrons*. Has often been treated as conspecific with second, but differences exist in plumage, habitat choice and, reputedly, vocalizations. Sometimes believed to be conspecific with third of those species; study needed of circumstances in apparent small range of overlap. Races intergrade to large extent; specimen from E Colombia described as a separate race, "*caquetanus*", but considered to represent subadult of *orenocensis*. Four subspecies recognized.

**Subspecies and Distribution.**

*V. a. orenocensis* Berlepsch & Hartert, 1902 - SE Colombia, S Venezuela and N Brazil.

*V. a. hiliaris* (Cabanis & Heine, 1863) - E Ecuador, E Peru and W Brazil S to N Bolivia and W Mato Grosso.

*V. a. ruficeps* (Spix, 1824) - C & NE Brazil S to Mato Grosso.

*V. a. affinis* (Swainson, 1821) - E Brazil (Alagoas and E Bahia).

**Descriptive notes.** c. 15-18 cm; 32-44 g. Male has cinnamon-buff lower forehead and lores, black upper forehead and crown with feathers broadly tipped red, becoming golden-yellow on nape and hindneck and slightly on to feather edges of upper neck side; dark buffish ear-coverts streaked olive, buffish chin and malar region; yellowish-green upperparts with variable red suffusion, pale yellow shaft streaks, rump and uppertail-coverts variably barred; wing-coverts with yellowish subterminal spots, reddish tips; dark brown flight-feathers broadly edged green, broadest on tertials, barred buffish-white on primaries and secondaries;

uppertail dark brown, barred yellowish, central pair often plain; light cinnamon-buff below, whiter on lower underparts, all barred dark olive-brown, dark bars more widely spaced on belly and flanks; underwing barred dark brown and whitish; longish bill straight, broad across nostrils, blackish, paler lower mandible; iris brown to red-brown; legs olive-grey to green-grey. Female has crown dark olive-brown, golden-yellow streaks on hindcrown merging with golden nape. Juvenile as adult, but face darker, more streaked, both sexes with red on crown, on female generally restricted to central area. Race *orenocensis* is greener, less yellow, above, shaft streaks much fainter, usually less red tinge; *hiliaris* is larger than previous, more bronzy or yellow above, has prominent broad red tips on wing-coverts; *ruficeps* is same size as last, but wing-covert markings much larger, pale shaft streaks on upperparts often more obvious. Voice. Series of up to c. 10-14 high-pitched nasal "ghi" or "kih" notes given infrequently.

**Habitat.** Tall rainforest; less common in forest edge, second growth and scrub; in humid lowland terra firme forest, to lesser extent in várzea forest, in Ecuador and Peru. Occasionally forages out into riparian forest and woodland, also visits trees in clearings. Occurs at 100-500 m in Venezuela;

to 500 m on E slope and 1000 m on Pacific slope in Colombian Andes; to 850 m but mostly 600 m in Ecuador; to 1300 m in Peru.

**Food and Feeding.** Arthropods; also fond of fruit. Forages singly, only occasionally in pairs; regular in mixed-species flocks. Foraging strata mostly high, from canopy down to middle levels; sometimes to lower levels, especially at forest edge. Accompanies army-ant processions to obtain flushed arthropods.

**Breeding.** Presumed to be Jan-Sept. No information.

**Movements.** Apparently resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally fairly common in Ecuador; uncommon in Peru. Occurs in Manu National Park (Peru), Murici Reserve, Sooretama Biological Reserve, Parque Estadual da Pedra Talhada and Rio Cristalino Private Reserve (Brazil). Very poorly known. Possibly not uncommon but overlooked.

**Bibliography.** Allen (1995), Balchin & Toyne (1998), Borges *et al.* (2001), Brace *et al.* (1997), Clements & Shany (2001), Donahue (1994), Friedmann (1948), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Munn (1985), Oren & Parker (1997), Parker & Goerck (1997), Parker *et al.* (1982), Peres & Whittaker (1991), Remsen *et al.* (1986), Ridgely & Greenfield (2001), Robinson & Terborgh (1997), Sargeant (1994), Short (1974c, 1985b), Sick (1993), da Silva (1996), Smith (1983), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Tobias *et al.* (1993), Zimmer (1930, 1942).

**134. Yellow-eared Woodpecker**

*Veniliornis maculifrons*

**French:** Pic à oreilles d'or      **German:** Goldohrspecht      **Spanish:** Carpintero Orejigualdo

**Taxonomy.** *Picus maculifrons* Spix, 1824, Rio de Janeiro, Brazil.  
Forms a superspecies with *V. kirkii*, *V. chocoensis*, *V. cassini* and *V. affinis*. Monotypic.

**Distribution.** E Brazil from SE Bahia S to Rio de Janeiro.

**Descriptive notes.** c. 15 cm. Male has brown forehead and crown feathers, tipped whitish on forehead, streaked white and tipped red on forecrown (red lost when worn), becoming largely red on hindcrown, pale golden-yellow nape and neck side; thin pale supercilium from rear upper edge of eye barely visible; olive-brown ear-coverts streaked whitish; whitish chin and malar region spotted or barred olive, usually very thin white moustachial line; yellowish-green upperparts sometimes

slightly bronzey, with yellow spots or bars, rump more distinctly barred, median wing-coverts with faint streaks or spots; darkish brown flight-feathers barred pale yellow to white; uppertail dark brown, barred paler; off-white underparts all narrowly barred olive, dark bars broader on breast and flanks, underwing barred brown and white; undertail as above, but barring stronger; long bill straight, quite broad across nostrils, blackish, paler base; iris deep brown to reddish; legs olive or grey. Distinguished from similar *V. affinis* by darker forehead, brighter upperparts with yellow bars and no red tinges. Female differs from male in having crown olive with pale spots, golden tips on hindcrown merging with yellow nape. Juvenile duller and more barred above than adult, with duller yellow nape, barring below more irregular and coarser, crown possibly with some red at front but insufficient details available. **Voice.** Long series of vibrating sonorous "ew" notes, rising and then falling; different call reported in breeding season, but no details. **Drums.**

**Habitat.** Secondary forest and parks in lowlands and hills.

**Food and Feeding.** No information available.

**Breeding.** No information. Presumably breeds in Sept-Oct.

**Movements.** Probably resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Atlantic Forest Lowlands EBA. A very little-known woodpecker, but appears to be common in at least S part of range. Occurs in Serra dos Órgãos National Park, in Nova Lombardia Biological Reserve, and in Sooretama Biological Reserve. Research and field studies required to determine its ecology and breeding biology. Attempts to determine and subsequently monitor this species' population in this unique Brazilian habitat would appear to be desirable.

**Bibliography.** Alves *et al.* (1997), Buzzetti (2000), Mallet-Rodrigues *et al.* (1997), Mazar Barnett & Kirwan (2001), Meyer de Schauensee (1982), Olrog (1968), Parker & Goerck (1997), Ruschi (1979), Sargeant & Wall (1996), Scott & Brooke (1985), Short (1985b), Sick (1993), da Silva (1996), Souza (1999), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Tobias *et al.* (1993), Venturini *et al.* (2001).

PLATE 38

## PLATE 38

## Family PICIDAE (WOODPECKERS) SPECIES ACCOUNTS

### Genus *PICULUS* Spix, 1824

#### 135. Rufous-winged Woodpecker

##### *Piculus simplex*

French: Pic à ailes rousses

German: Zimtflügelspecht

Spanish: Carpintero Alirrufo

**Taxonomy.** *Chloronerpes simplex* Salvin, 1870. Bugaba, Chiriquí, Panama.

May form a superspecies with *P. callopterus*, *P. litae* and *P. leucolaemus*; all four have often been treated as conspecific. Proposed race *allophyeus*, from Honduras, known from only two specimens; further study needed. Monotypic.

**Distribution.** E Honduras S to Costa Rica and W Panama (W Chiriquí, W Bocas del Toro, Atlantic slope of Veraguas).

**Descriptive notes.** c. 18 cm; 51-55 g. Male has red forehead to hindneck, red lores, very broad red malar band; brownish-green ear-coverts, sometimes some red feather tips towards eye; pale brownish-green chin; bronze-green upperparts, including wing-coverts and tertials; flight-feathers mostly cinnamon-rufous, dark olive-brown outer webs and bars on inner webs; uppertail blackish, often an element of cinnamon-rufous in outer feathers; olive-green throat and upper breast, feathers of upper breast with pale buffish-yellow subterminal spots or wedges and darker tips, pale yellow-buff lower

breast to undertail-coverts barred dark olive; underwing-coverts cinnamon-rufous; fairly short bill slightly curved on culmen, relatively narrow across nostrils, blackish, paler grey lower mandible; iris pale bluish or yellowish to white; legs olive to greyish. Distinguished from *P. callopterus* by pale eyes, lack of pale stripe above malar. Female differs from male in having head mostly plain brownish-olive, red confined to nape and hindneck. Juvenile duller, greyer and greener, with throat to breast mottled or spotted buffish-green, barring below uneven, often a very short narrow yellowish-white stripe above malar, male with red

only on rear crown to hindneck. **VOICE.** Loud, sharp, nasal "deecah", more drawn out and higher than note of *P. rubiginosus*; loud, emphatic series of slightly nasal downslurred "heew" notes. Drums in long bursts.

**Habitat.** Canopy and edge of humid forest, sometimes large trees in adjacent semi-open terrain. Lowlands and foothills, locally to 750 m on Caribbean slope, to 900 m on Pacific slope.

**Food and Feeding.** Ants, beetles and their larvae. Occurs singly, less often in pairs; occasionally accompanies mixed-species flocks. Forages high in trees, but also at or below middle levels; prefers forest interior rather than edge. Pecks into mossy and rotting branches, lianas, and dead wood trapped in vine tangles; taps incessantly and irregularly.

**Breeding.** Feb-May. Nest-hole excavated 2.5-5 m up in recently dead tree or rotten stub. Clutch 2-4 eggs; no other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common. Occurs in Braulio Carrillo National Park and Guayabo National Monument, in Costa Rica.

**Bibliography.** Anon. (1998b), Blake & Loiselle (2000, 2001), Monroe (1968), Ridgely & Gwynne (1989), Skutch (1981), Stad (1960, 1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a), Young *et al.* (1998).

## 136. Stripe-cheeked Woodpecker

### *Picus callopterus*

**French:** Pic bridé **German:** Panamaspecht **Spanish:** Carpintero Panameño

**Taxonomy.** *Chloronerpes callopterus* Lawrence, 1862, Lion Hill, Canal Zone, Panama.

May form a superspecies with *P. simplex*, *P. litae* and *P. leucolaemus*, and all four often treated as conspecific. Monotypic.

**Distribution.** WC to E Panama: Veraguas, and Caribbean slope of Canal Zone to Darién.

**Descriptive notes.** c. 17 cm. Male has red forehead to hindneck, greenish-yellow lores and side of head, short narrow yellowish-white stripe from lores to lower edge of ear-coverts, broad red malar band back to neck side; pale greenish chin; bronze-green upperparts, including wing-coverts and tertials; mostly cinnamon-rufous flight-feathers, dark olive-brown outer webs and bars on inner webs; uppertail blackish, often some cinnamon-rufous on outer feathers; greenish-olive throat and upper breast, pale yellowish spots on breast tending to form bar-like pattern, rest of underparts pale yellow with greenish-olive barring; underwing-coverts

with some cinnamon-rufous; fairly short bill, culmen slightly curved, rather narrow across nostrils, blackish, paler lower mandible; iris red-brown to dark brown; legs olive-grey. Differs from *P. simplex* in dark eyes, yellow cheekstripe, more barred pattern on breast. Female has red on head restricted to rear. Juvenile duller than adult, more irregularly barred below, with mottled or barred upper breast, males without red moustache and crown. **VOICE.** No documented information; said to differ from that of *P. simplex*.

**Habitat.** Humid forest and forest borders in foothills on Caribbean slope, between 300 m and 900 m. **Food and Feeding.** Small ants are only food items on record. Usually found singly or in pairs, also with mixed-species flocks. Forages on lower or middle parts of trees; pecks steadily.

**Breeding.** No relevant information available.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Central American Caribbean Slope EBA and Darién Lowlands EBA. Uncommon and local. Poorly known species; research required on its breeding behaviour and other details.

**Bibliography.** Anon. (1998b), Ridgely & Gwynne (1989), Robbins *et al.* (1985), Stattersfield *et al.* (1998), Wetmore (1968a).

## 137. Lita Woodpecker

### *Picus litae*

**French:** Pic de Lita **German:** Litaspecht **Spanish:** Carpintero de Lita

**Taxonomy.** *Chloronerpes litae* Rothschild, 1901, Lita, Ecuador.

May form a superspecies with *P. simplex*, *P. callopterus* and *P. leucolaemus*, and all four have often been treated as conspecific. Frequently lumped with *P. leucolaemus*, but differs significantly in plumage details; possibly not even closely related. Includes SW Colombian birds formerly thought to represent an undescribed race of *P. flavigula*. Monotypic.

**Distribution.** W Colombia (Pacific slope of N Andes, middle Magdalena Valley) S to NW Ecuador (S to NW Pichincha).

**Descriptive notes.** c. 17-18 cm. Male has red forehead to hindneck, golden-yellow lores to ear-coverts and neck side, broad red malar with thin olive-yellow stripe below; dusky olive chin and throat with small white spots, appearing blackish in field; olive-yellow to bronze-green upperparts, including wing-coverts and tertials, yellow feather tips in fresh plumage, rump slightly darker; dark brown flight-feathers tipped black, outer webs edged olive, pale cinnamon-rufous area on inner webs; uppertail blackish, feathers edged greenish; whitish below with black wedge-shaped bars; underwing rufous, coverts paler; shortish bill pointed, culmen

slightly curved, broad across nostrils, light bluish, black tip; iris dark brown; legs dark slate-blue. Distinguished from similar *P. leucolaemus* by smaller size, darker red on crown, more yellow on head, darker chin and throat. Female differs from male in having entire head yellow apart from red nape and malar. Juvenile duller and greener than adult, without red malar or head top, less yellow on head side, streaked throat. **VOICE.** Hissing "shreeyr" or "peesh", very like that of *P. leucolaemus* and *P. flavigula*.

**Habitat.** Humid and wet forest, also forest edges and mature second growth; in lowlands and foothills, to c. 800 m.

**Food and Feeding.** No details of diet; presumably insects and larvae. Forages singly, occasionally in pairs, in subcanopy and middle levels of forest.

**Breeding.** Very little information. Single observation, in Aug, of male excavating two holes 8 m and 10 m up large dead tree, with female in attendance; another possible nest in Jul.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Chocó EBA. Uncommon to locally common. Occurs in El Pangán Reserve (Colombia). Very poorly known; easily overlooked as it tends to remain in forest subcanopy; additional research and field study required. Extensive deforestation has occurred in range, and appears to be continuing unabated. In view of this, and the very small range, species should perhaps be considered Near-threatened.

**Bibliography.** Ridgely & Greenfield (2001), Ridgely *et al.* (1998), Rodner *et al.* (2000), Salaman (1994), Stattersfield *et al.* (1998).

## 138. White-throated Woodpecker

### *Picus leucolaemus*

**French:** Pic à gorge blanche **German:** Weißkehlspecht **Spanish:** Carpintero Gorgiblanco  
**Other common names:** Rufous-winged Woodpecker(!)

**Taxonomy.** *Picus leucolaemus* Natterer and Malherbe, 1845, Brazil.

May form a superspecies with *P. simplex*, *P. callopterus* and *P. litae*; all four have often been treated as conspecific. Present species frequently lumped with *P. litae*, but differs significantly in plumage and possibly not even closely related. Depth of plumage coloration varies slightly, but with no obvious geographical pattern. Monotypic.

**Distribution.** S Colombia (Serranía de Churumbelos, in E Cauca) and E Ecuador E to W & C Amazonian Brazil and S to SE Peru and N Bolivia.

**Descriptive notes.** c. 19-20 cm; 69 g. Male has bright red forehead to hindneck, yellowish-green ear-coverts bordered below by golden-yellow band from bill base to rear neck side, broad red malar region; white chin and throat; bronze-green upperparts, wing-coverts and tertials, feathers tipped and edged yellow when fresh; dark brown flight-feathers, pale cinnamon-rufous on inner webs; uppertail blackish, edged greenish; yellowish-green upper breast with paler feather centres and darker tips, lower breast to undertail-coverts white with olive bars, underwing-coverts cinnamon; fairly short bill pointed, culmen slightly curved, broad across nostrils, blackish to grey; iris dark brown to red-brown; legs dark olive to blackish. Distinguished from similar *P. litae* by slightly bigger size, less yellow on head, all-white chin and throat. Female has red on head restricted to small nape patch. Juvenile greener than adult, without male's red malar and crown. **VOICE.** Harsh sibilant "piiss" or "shreeyr", heard infrequently.

**Habitat.** Tall, humid terra firme forest and lowland várzea forest along rivers; recorded at edge of primary forest and in second growth in Colombia. Lowlands and foothills, to 1000 m in Ecuador and to 1400 m in Peru.

**Food and Feeding.** Diet not recorded; presumably insects and their larvae. Usually forages singly, occasionally in pairs; will join mixed flocks. Forages in canopy down to mid-levels. Probes, flakes off bark.

**Breeding.** No information.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Rare to locally uncommon in Ecuador; recent records from only seven sites. Uncommon in Peru; occurs in Manu National Park and surrounding area. First recorded in Colombia in 1998; possibly overlooked previously. A poorly known species. Uncertainty over its taxonomic position has made assessment of any past records very difficult.

**Bibliography.** Allen (1995), Angehr & Aucca (1997), Balchin & Toyne (1998), Brace *et al.* (1997), Butler (1979), Clements & Shany (2001), Donahue (1994), Duhs (1992), Hilty (1997), Hilty & Brown (1986), Hornbuckle (1999), Mazar Barnett & Kirwan (1999), Meyer de Schauensee (1982), Olrog (1968), Parker *et al.* (1982), Perry *et al.* (1997), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely *et al.* (1998), Robinson & Terborgh (1997), Sick (1993), da Silva (1996), Stotz *et al.* (1996), Terborgh *et al.* (1984), Willis & Oniki (1990).

## 139. Yellow-throated Woodpecker

### *Picus flavigula*

**French:** Pic à gorge jaune **German:** Gelbkehlspecht **Spanish:** Carpintero Gorgigualdo

**Taxonomy.** *Picus flavigula* Boddaert, 1783, Cayenne.

E race *erythropis*, with distinctive plumage and different habitat preferences, possibly a separate species. Race *magnus* intergrades with nominate in NE Brazil. Birds from SW Colombia, previously thought to represent an undescribed race of present species, have now been reidentified as *P. litae*. Three subspecies recognized.

**Subspecies and Distribution.**

*P. f. flavigula* (Boddaert, 1783) - Extreme E Colombia, S Venezuela and the Guianas, S to N Amazonia. *P. f. magnus* (Cherrie & Reichenberger, 1921) - SE Colombia, NE Ecuador and Amazonian Brazil S to E Peru, NE Bolivia and Mato Grosso.

*P. f. erythropis* (Vieillot, 1818) - E Brazil in Pernambuco and from Bahia to São Paulo.

**Descriptive notes.** 19-20 cm; 44-63 g (*flavigula*). Male has bright red forehead to nape with dark feather bases, yellowish-green lores, short red malar band; rest of head, including chin and throat, bright golden-yellow; entire upperparts yellowish-green, brighter on mantle and back, occasionally a few paler spots on rump; brownish-black flight-feathers, inner webs with cinnamon patches; uppertail black, edged greenish; green below, breast with whitish feather centres and dark tips, pattern more barred or scaly on belly and undertail-coverts; underwing with paler coverts somewhat barred; shortish bill pointed, culmen slightly curved, narrow across

nostrils, black, paler base; iris brown; legs dark green-grey. Female lacks red on crown and malar,

having these areas more golden to yellow with green tips. Juvenile duller and greener above than adult, less yellow on head, darker and less marked below but still yellow throat, male sometimes with some red on crown, female with crown entirely green. Race *magnus* has malar area golden-yellow in both sexes; *erythropis* is smaller than others, distinctive, male with red extending variably over neck side and from malar over chin and throat, female with golden-yellow forecrown, malar and throat, throat usually with red markings, both with entire underparts more barred than spotted or scaly. Voice. Far-carrying hissing "queea" or "shaa, gheh" or "shreyr", sometimes doubled, given at infrequent intervals; rattle-type call "kee" in series 6-8 seconds long, slowing towards end.

**Habitat.** Tall, humid *terra firme* forest and seasonally inundated *várzea* forest along rivers; also forest edge. Also drier forest types (*caatinga*) in E Brazil. Lowlands; below 300 m in Ecuador, to 500 m in Peru.

**Food and Feeding.** Mainly ants (*Camponotus*, *Pheidole*, *Crematogaster*) recorded in diet. Met with singly, in well-separated pairs, or in mixed-species flocks. Forages at middle levels in subcanopy up to treetops, on limbs, branches and trunks. More vigorous feeding techniques, such as pecking and hammering, seem to be commonest; flakes off pieces of bark, also probes.

**Breeding.** Probably breeds in Nov in Colombia and Venezuela; May-Jul in the Guianas, and Aug-Dec in Brazil to Bolivia. Hole built in stub, apparently not very high up, rarely to 15 m. Clutch size and incubation and fledging periods not documented.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rather common throughout most of range; rare to uncommon in Ecuador and Peru. Occurs in Canaima National Park and Imataca Forest Reserve and El Dorado (Venezuela), Cuyabeno Reserve (Ecuador) and Serra dos Órgãos National Park, Rio Cristalino Private Reserve and Sooretama Biological Reserve (Brazil).

**Bibliography.** Aleixo (1997), Aleixo & Galetti (1997), Allen (1995), Buzzetti (2000), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Donahue (1994), Ferreira de Vasconcelos & Melo-Júnior (2001), Figueiredo & Lo (2000), Friedmann (1948), Goerck (1999), Guix *et al.* (1999), Haverschmidt & Mees (1994), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Oren & Parker (1997), Parker & Goerck (1997), Parker *et al.* (1982), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Scott & Brooke (1985), Sick (1993), da Silva (1996), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Thiollay & Jullien (1998), Tostain *et al.* (1992).

## 140. Golden-green Woodpecker

### *Piculus chryschloros*

**French:** Pic vert-doré      **German:** Bronzespecht      **Spanish:** Carpintero Verdiamarillo

**Taxonomy.** *Piculus chryschloros* Vieillot, 1818, Paraguay and Brazil.

Forms 3 superspecies with *P. aurulentus*. Specific name sometimes misspelt as *chryschloros*. Racial differentiation partly obscured by considerable individual variation; birds in S Colombia (Putumayo) and NE Ecuador lacking red malar stripe may possibly represent a new, as yet unnamed race; further study needed, possibly also taxonomic revision. Nine subspecies recognized.

**Subspecies and Distribution.**

*P. c. aurosus* (Nelson, 1912) - E Panama.

*P. c. xanthochlorus* (P. L. Sclater & Salvin, 1875) - N Colombia and NW Venezuela.

*P. c. capistratus* (Malherbe, 1862) - SE Colombia and NW Brazil E to Surinam.

*P. c. guianensis* Todd, 1937 - French Guiana.

*P. c. paraensis* (Snethlage, 1907) - NE Brazil.

*P. c. laemostictus* Todd, 1937 - NW Brazil.

*P. c. hypochryseus* Todd, 1937 - W Brazil S to N Bolivia.

*P. c. chryschloros* (Vieillot, 1818) - C & S Brazil S to E Bolivia, W Paraguay and N Argentina (Formosa S to Santa Fe).

*P. c. polyzonus* (Valenciennes, 1826) - SE Brazil (Espírito Santo, Rio de Janeiro).

**Descriptive notes.** 18-21 cm (*chryschloros*), 26-27 cm (*capistratus*, *polyzonus*); 55 g (*chryschloros*), 62-91 g (*capistratus*). Male has red forehead to nape, olive-green lores, area around eye, ear-coverts and rear neck side, pale yellow stripe from lower lores to hindneck, short red malar band bordered below by olive-green stripe; yellow chin and upper throat; olive-green upperparts, darker olive-brown wings; uppertail dark olive-brown; pale yellow-buff underparts entirely barred olive-brown, underwing largely cinnamon; longish bill slightly curved, broad across nostrils, dark grey to blackish, paler base; iris white or bluish-white; legs greyish-green. Differs from *P. aurulentus* in yellower underparts, lack of yellow stripe behind eye. Female lacks red on head, has forehead to nape olive, malar olive-brown. Juvenile much as respective adult, but duller, less regularly marked, darker eyes. Races differ greatly in size and plumage: *aurosus* is small, very yellow in tone, golden-yellow throat, yellow ground colour below, female with yellow crown; *xanthochlorus* is similar to previous, but generally duller in colour; *capistratus* is very large, darker, more olive-green, with less red in malar, barred throat, whitish to pale greenish-white ground colour below; *guianensis* resembles last, but usually has unbarred throat; *paraensis* is intermediate in size, has deeper golden or cinnamon-buff cheekstripe and throat, and often entire ground colour of underparts, male with green (not red) malar, female with greenish-yellow crown; *laemostictus* is quite big, rather dark, less yellow, with plain whitish throat; *hypochryseus* is very like previous, perhaps slightly larger; *polyzonus* is large, with pale yellow cheekstripe, unmarked pale yellow throat, yellow ground colour below, sometimes barred pale primary coverts. Voice. Shrill sibilant "shreer", sometimes doubled, uttered infrequently.

**Habitat.** Humid *terra firme* and *várzea* forest, rainforest, also deciduous forest, patches of wood in savanna and in xerophytic vegetation; also visits forest edge, tall trees in clearings and pastures, often near water or marshy ground. Lowlands; to 450 m in NW Venezuela and at 100-650 m in S; to 500 m in Colombia; mostly below 300 m but locally to 600 m in Ecuador, and to 650 m in Peru.

**Food and Feeding.** Ants (*Camponotus*) and termites (Isoptera) recorded. Forages singly, in pairs, or in mixed-species flocks. Forages rather high in subcanopy of forest interior, sometimes lower; ventures to edge or into open or semi-open. Gleaning seems to be commonest feeding technique; also pecks, and excavates to obtain subsurface prey, with intensive use of the tongue.

**Breeding.** Records from Colombia suggest breeding in Feb-Mar; in Sept in Argentina. Nest-hole in tree or in arboreal nest of insects. No data on clutch size and incubation and fledging periods.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Status uncertain, possibly not uncommon in much of range. Rare to uncommon and local in Ecuador; uncommon in Peru. Occurs in several protected areas, including Tayrona National Park (Colombia), Cuyabeno Reserve (Ecuador) and Rio Cristalino Private Reserve (Brazil). Despite large range, this species is not particularly well known. Further research required on its taxonomy, which may possibly indicate that some populations should be regarded as separate species; in that case, status of these would need to be established.

**Bibliography.** Allen (1995), Brace *et al.* (1997), Canevari *et al.* (1991), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Contreras *et al.* (1990), Donahue (1994), Friedmann (1948), Haverschmidt & Mees (1994), Hayes (1995), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Munn (1985), Oren & Parker (1997), Parker & Goerck (1997), de la Peña (1994), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Robinson & Terborgh (1997), Scott & Brooke (1985), Short (1974b, 1975), Sick (1993), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Thiollay & Jullien (1998), Tostain *et al.* (1992), Wetmore (1926, 1968a).

## 141. Yellow-browed Woodpecker

### *Piculus aurulentus*

**French:** Pic à bandeaux      **German:** Weißbrauenspecht      **Spanish:** Carpintero Cejigualdo  
**Other common names:** White-browed Woodpecker

**Taxonomy.** *Piculus aurulentus* Temminck, 1821, Paraguay and Brazil.

Forms a superspecies with *P. chryschloros*. Monotypic.

**Distribution.** SE Brazil (São Paulo, E Minas Gerais and W Espírito Santo S to Rio Grande do Sul), E Paraguay and NE Argentina (Misiones, NE Corrientes).

**Descriptive notes.** 21-22 cm; 22-68 g. Male has bright red forehead to nape with very thin olive border, narrow pale yellowish-white supercilium from eye to nape side; dark olive-green area around eye, ear-coverts and rear neck side, pale yellow band from lores to neck side, red malar stripe becoming green at rear; pale golden chin and throat, often some red on side of chin; olive-green hindneck and upperparts, including tertials, sometimes with faint bronze tinge; dark brown flight-feathers edged greenish, dark-barred cinnamon-rufous patch on inner webs; uppertail blackish; whitish underparts densely and broadly barred dark

olive, cinnamon-rufous underwing mostly barred black; medium-length bill slightly curved on culmen, fairly broad across nostrils, blackish-grey, paler base of lower mandible; iris chestnut-brown, orbital ring dark grey; legs greenish-grey. Distinguished from *P. chryschloros* by pale supercilium, whiter underparts with broader dark bars. Female differs from male in having forehead and crown olive, occasionally with golden tips, and only little red in malar. Juvenile much as respective adult, but duller, with coarser barring. Voice. Single, sharp loud note, and descending series of plaintive "eeeww" notes. Drums in rapid, regular rolls.

**Habitat.** Humid montane forest, forest edge, and dense second growth and woodland; also humid lowland forest. Present at 750-2000 m in Brazil, though generally lower in Paraguay and Argentina.

**Food and Feeding.** Ants and their larvae and eggs. Singly or in pairs. Forages in middle tiers, by gleaning and pecking.

**Breeding.** Sept in Argentina. Nest high up, to 7 m, in tree. No other information.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Considered Near-threatened. Rather uncommon; apparently shy in nature, and not often seen. Apparent extension towards S in Rio Grande do Sul recorded in 1994 and 1995, possibly overlooked previously. Occurs in Serra dos Órgãos and Itatiaia National Parks and Serra do Mar State Park (Brazil). Much of this species' forest habitat has already been lost, and surviving patches continue to be destroyed by clearance and uncontrolled fires; montane forest in SE Brazil appears to have remained more intact, providing a relatively safe refuge, but this situation could easily change for the worse. Further field studies required to determine more about this woodpecker's requirements, and monitoring of the population is desirable.

**Bibliography.** dos Anjos (2001), dos Anjos & Schuchmann (1997), dos Anjos *et al.* (1997), Belton (1984), Bencke & Kindel (1999), Brooks *et al.* (1993), Buzzetti (2000), Canevari *et al.* (1991), Efe *et al.* (2000), Ferreira de Vasconcelos & Melo-Júnior (2001), Figueiredo & Lo (2000), Goerck (1999), Guix *et al.* (1999), Hayes (1995), Lowen, Bartrina *et al.* (1996), Lowen, Clay *et al.* (1995), Madroño, Clay & Hostettler (1997), Madroño, Clay, Robbins *et al.* (1997), Maurício & Dias (1998), Meyer de Schauensee (1982), Olrog (1968), Pacheco *et al.* (1996), Parker & Goerck (1997), de la Peña (1994), do Rosário (1996), Saibene *et al.* (1996), Scott & Brooke (1985), Short (1985b), Sick (1993), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993).

# 142. Grey-crowned Woodpecker

## *Picus auricularis*

**French:** Pic à tête grise **German:** Graukappenspecht **Spanish:** Carpintero Cabecigrís

**Taxonomy.** *Chloronerpes auricularis* Salvin and Godman, 1889, Xautipa, Sierra Madre del Sur, Guerrero, Mexico.

Forms a superspecies with *P. rubiginosus*, and sometimes considered conspecific. Greyer birds from SE Sonora, named as race *sonoriensis*, unacceptable, based on worn specimens. Monotypic.

**Distribution.** Pacific slope of W Mexico, from S Sonora to Oaxaca.

**Descriptive notes.** c. 16-17 cm; 52-68 g. Male has grey to green-grey forehead to nape, often red at crown and nape sides, buff lores, area around eye and ear-coverts, red malar stripe, sometimes also small red patch on lores; olive neck side and hindneck barred paler; chin and throat streaked or barred olive and white; green to greyish-green upperparts, greyer when worn, faintly barred, wing-coverts tinged deep golden-bronze; darker flight-feathers with greenish-yellow area on inner webs; uppertail brown, feathers edged greenish; pale cream-white to yellowish below with broad dark olive bars, densest on breast, pale yellowish

underwing, yellow undertail; medium-length bill straight, narrow, blackish; iris hazel-brown; legs green-grey. Distinguished from *P. rubiginosus* by smaller size, no red on nape. Female differs in having malar barred olive and whitish, not red. Juvenile duller than adult, with less regular barring, male with grey in malar. **VOICE.** Single explosive "kee-ah", mewing "growh"; also rapid shrill rattle, similar to that of *P. rubiginosus*.

**Habitat.** Humid to mesic forests and forest edge; locally also highland pine-oak (*Pinus-Quercus*) forest and tropical deciduous oak forest. Lowlands to foothills, mostly from 900 m to 2400 m.

**Food and Feeding.** Little information. Diet includes berries; forages from high levels down to low ones.

**Breeding.** No data. Probably similar to *P. rubiginosus*.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common. Very poorly known species; requires field research to determine various aspects of its behaviour. No known threats, but little information.

**Bibliography.** Anon. (1998b), Baptista (1978), Binford (1989), Friedmann *et al.* (1957), Hernández *et al.* (1995), Howell & Webb (1995), Hutto (1980, 1992), Peterson & Navarro-Sigüenza (2000), Schaldach (1963), Short (1985b), Stotz *et al.* (1996).

# 143. Golden-olive Woodpecker

## *Picus rubiginosus*

**French:** Pic or-olive **German:** Olivmantelspecht **Spanish:** Carpintero Oliváceo  
**Other common names:** Green Woodpecker(!), Blue-headed Woodpecker; Bronze-winged Woodpecker (*aeruginosus* group)

**Taxonomy.** *Picus rubiginosus* Swainson, 1820, Caracas, Venezuela.

Forms a superspecies with *P. auricularis*, and sometimes regarded as conspecific. N races *aeruginosus* and *yucatanensis* possibly represent a distinct species, apparently differing in vocalizations. Considerable individual variation in coloration and pattern, making defining and delimitation of races difficult; those listed best regarded as a tentative general guide, requiring clarification through further research. Additional named races include *maximus* (E & C Pacific highlands of SE Mexico and Guatemala), *differens* (Pacific slope of Guatemala), *uropygialis* (mountains of Costa Rica and W Panama), and in Colombia *pacificus* (W Andes), *michaelis* (SE Nariño), *palmitae* (W slope of E Andes in N) and *nuchalis* (E slope of Andes near Ecuador border), all of which fall within range of variation of other races. Nineteen subspecies recognized.

**Subspecies and Distribution.**

- P. r. aeruginosus* (Malherbe, 1862) - E Mexico (Tamaulipas to Veracruz).
- P. r. yucatanensis* (Cabot, 1844) - S Mexico (from Oaxaca) S to W Panama.
- P. r. alleni* (Bangs, 1902) - N Colombia (Santa Marta area).
- P. r. meridensis* (Ridgway, 1911) - NW Venezuela.
- P. r. rubiginosus* (Swainson, 1820) - NC & NE Venezuela.
- P. r. tobagenis* (Ridgway, 1911) - Tobago.
- P. r. trinitatis* (Ridgway, 1911) - Trinidad.
- P. r. deltanus* Alvedo & Ginés, 1953 - Delta Amacuro in NE Venezuela.
- P. r. paraquensis* Phelps, Sr. & Phelps, Jr., 1947 - mountains of SC Venezuela.
- P. r. viridissimus* Chapman, 1939 - Auyán tepui in SE Venezuela.
- P. r. guianae* (Hellmayr, 1918) - E Venezuela and adjacent Guyana.
- P. r. nigriceps* Blake, 1941 - Acarai Mts of S Guyana and adjacent S Surinam.
- P. r. gularis* (Hargitt, 1889) - W & C Andes in Colombia.
- P. r. rubripileus* (Salvadori & Festa, 1900) - SW Colombia, W Ecuador and NW Peru.
- P. r. buenavistae* (Chapman, 1915) - E Andes in Colombia and E Ecuador.
- P. r. coloratus* (Chapman, 1923) - extreme SE Ecuador and NC Peru.
- P. r. chrysogaster* (Berlepsch & Stolzmann, 1902) - C Peru.
- P. r. canipileus* (d'Orbigny, 1840) - C & SE Bolivia.
- P. r. tucumanus* (Cabanis, 1883) - S Bolivia to NW Argentina (S to Tucumán).

**Descriptive notes.** c. 18-23 cm; 51-68 g (*trinitatis*), 51-72 g (*meridensis*), 69-82 g (*aeruginosus*), 74-84 g (*gularis*), 77-88 g (*rubripileus*), 78-86 g (*yucatanensis*). Male has dark slate-grey forehead and crown with narrow red border, red nape, pale buff to whitish lores, area around eye and ear-coverts, broad red malar stripe expanding slightly at rear; neck side barred yellow-buff and olive; pale buffish-white chin and upper throat heavily streaked blackish; green upperparts and tertials with slight bronze tinge, rump and uppertail-coverts paler with dark olive barring; dark brownish-olive flight-feathers edged green, yellowish on shafts extending slightly on to inner webs of primaries; uppertail brown; pale buffish-yellow underparts entirely barred blackish-olive, bars closest on breast; underwing largely

yellow; medium-length bill broad, culmen curved, slaty to black; iris deep dull red; legs grey to olive-grey. Female lacks red on crown side and malar, has latter streaked like throat. Juvenile much as respective adult but much duller, with pattern less regular. Races differ greatly in size, also in plumage tone, strength of barring below, throat colour, and amount of red on male's crown, but much variation: *aeruginosus* is larger than nominate, proportionately long-tailed, has distinctly green back, bronze-edged green wings, less barred rump, blackish breast with pale scallop-like markings rather than bars, male with less red on side of crown, female

with narrower U-shaped red band; *yucatanensis* is similar to last, but more red on side of crown, coarsely barred breast less dark, variable, tends to be slightly larger and greener in highlands than in lowlands, and lowland populations decrease in size from N to S; *alleni* is large, bronze-gold with some red tinges above, has rump more or less unbarred, white-spotted black throat, narrow blackish breast bars, male with moderate red on crown; *tobagenis* resembles last, but breast bars less black, more green, and broader; *trinitatis* is much smaller than previous, with less heavy bill; *deltanus* is small, with greener back, larger white throat spots; *paraquensis* is large, has strong bronze tinge to back, very dark crown with much-reduced red, some females with no red in crown; *viridissimus* is very large, bright yellow-green on back, breast has whitish ground colour, very black broad barring, male with much less red on head; *guianae* is smaller than previous, with back more bronzy, very fine pale spots on black throat, moderate red in crown; *nigriceps* resembles last, but bronze tinge more or less lacking; *buenavistae* is very large, has back bronzy with reddish tinge, well-barred rump, bars below olive-green; *meridensis* is somewhat smaller than last, with less bronzy back; *gularis* is rather large, has black throat finely spotted white (rarely, no spots), rather pale underparts, male with forehead to nape entirely red, female with slightly less red; *rubripileus* as previous but smaller, with breast bars blacker; *coloratus* has bright yellow belly with barred flanks, is only slightly bronzy above; *chrysogaster* has yellow belly unbarred, back very bronzy with red tinge, male usually with much red on crown; *canipileus* is similar to last, but belly weakly barred; *tucumanus* is large, with thin bill, duller green back less bronzy, whiter underparts, blackish barring. **VOICE.** Loud, clear "dree" repeated c. 6 times in 2-3 seconds, higher-pitched and faster than that of *Melanerpes*, as long-distance call; also single sharp "deeeeh", "geep" or "keeah"; also "churr", "choo-úr" (first note longer than second); liquid "woick-woick-woick" or "utzia-deek" in interactions; low whirring notes in intimate contacts; race *aeruginosus* sharp "kyown" singly or in short series, also sharp "weeyk" or "wheer" in series of 10 notes per 4-6 seconds, also short low chatter.

**Habitat.** Wide range of habitats occupied, both humid and dry. Rainforest and cloudforest, dry cloudforest, heavy epiphyte-laden forest, and their edges, also adjacent clearings and semi-open parts with scattered trees, and second growth; also oak-pine (*Quercus-Pinus*) woodland, dry deciduous oak forest, riparian thickets, mangroves; commonly associated also with trees bordering fields and coffee plantations with shade trees, as well as with clearings with scattered trees in mountainous terrain. In Mexico, race *aeruginosus* occurs in lowlands and foothills with cottonwoods (*Populus*), mesquite (*Prosopis*) and cacti. From near sea-level and foothills to highlands; to 2100 m in Mexico; from 750 m, rarely 400 m, to 2150 m in Central America; 350-2100 m in Venezuela, but to 2800 m in N & NW and down to sea-level in Orinoco Delta; 900-3100 m in Colombia, and to 2300 m in Ecuador, Peru and Bolivia; at 1000-2500 m in Argentina.

**Food and Feeding.** Ants, termites (Isoptera), beetles and their wood-boring larvae; rarely, fruits and berries. Generally singly, or in pairs with partners maintaining loose contact; also in mixed-species groups. Forages in interior of forest, but most frequently seen in more open places near tall forest; often sits quietly on horizontal perch in top of a tree. Forages at middle levels to upper canopy; also descends lower, but seems not to feed on the ground. Explores limbs, branches and vines, and tree trunks; usually on large trees, also on low stubs and fence posts along hedgerows and edges. Moves slowly when working up a tree. Commonest techniques are pecking, hammering (live soft bark, soft green wood), pecking with probing, surface probing, prying into crevices; gleaning plays a minor role. In particular, probes among vines, dense foliage, or into clusters of epiphytes or on mossy branches; tears apart bromeliads to reach food items. Opens cocoa pods to obtain insects inside.

**Breeding.** Jan-May from Mexico to Colombia and Trinidad; recorded in Oct in Guyana and Ecuador. Hole excavated 1-2-18 m up in dead or live stub or tree, or in palm. Clutch 2-4 eggs; both sexes incubate, in long stints, period not documented; nestlings fed at long intervals, by regurgitation, male apparently making greater contribution; nestling period c. 24 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common throughout most of range; common to fairly common in Central America; fairly common on Pacific slope in Ecuador and Peru, less common on E side. Occurs in many protected areas in range, including El Triunfo and Ría Lagartos Biosphere Reserves (Mexico), Tikal National Park (Guatemala), Guayabo National Monument and Monteverde Biological Reserve (Costa Rica), La Planada, Río Nambí and El Pangán Reserves (Colombia), Henri Pittier, Macarao and Cueva de los Guácharos National Parks (Venezuela), Tinalandia Reserve (Ecuador), Asa Wright Nature Centre (Trinidad), Machu Picchu Historical Sanctuary (Peru), and El Rey and Calilegua National Parks (Argentina). This widespread species' ability to live in a wide variety of wooded habitats suggests that its future is secure.

**Bibliography.** Balchin & Toyn (1998), Baptista (1978), Barrowclough *et al.* (1995), Binford (1989), Bloch *et al.* (1991), Bond *et al.* (1989), Canevani *et al.* (1991), Chapman (1931), Clements & Shany (2001), Fjeldså & Krabbe (1990), Haverschmidt & Mees (1994), Heisler (1994), Herklots (1961), Hernández *et al.* (1995), Hilty (1997), Hilty & Brown (1986), Howell & Webb (1995), Ibáñez (2000), Krabbe *et al.* (1996), Meyer de Schauensee & Phelps (1978), Miller (1963), Monroe (1968), Nores *et al.* (2000), de la Peña (1994), Pople *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Rowley (1984), Salaman (1994), Schmitt *et al.* (1997), Short (1985b), Sick (1993), Skutch (1956, 1969a), Slud (1964), Snyder (1966), Stiles (1985), Stotz *et al.* (1996), Sutton (1953), Thiollay & Jullien (1998), Tostain *et al.* (1992), Walker (2001), Wetmore (1968a).

# 144. Crimson-mantled Woodpecker

## *Picus rivoli*

**French:** Pic de Rivoli **German:** Rotmantelspecht **Spanish:** Carpintero Candela

**Taxonomy.** *Picus Rivoli* Boissonneau, 1840, no locality = near Bogotá, Colombia.

Races rather poorly differentiated except for *atriceps*. Five subspecies recognized.

#### Subspecies and Distribution.

*P. r. rivolii* (Boissoneau, 1840) - NW Venezuela (Sierra de Perijá) S in Andes to EC Colombia.  
*P. r. meridae* (Chapman, 1923) - W Venezuela (Mérida, Táchira).  
*P. r. quindiana* (Chapman, 1923) - Andes of NC Colombia.  
*P. r. brevirostris* (Taczanowski, 1875) - SW Colombia S to C Peru.  
*P. r. atriceps* (P. L. Selater & Salvin, 1876) - SE Peru and W & C Bolivia.

**Descriptive notes.** 22-28 cm; 85-97 g (*brevirostris*), 100-112 g (*rivolii*). Male has black forehead to hindcrown feathers broadly tipped red, bright red nape, hindneck and lower neck side; pale yellowish lores, area around eyes and ear-coverts, black malar feathers broadly tipped red; black chin and upper throat speckled with white; red upperparts with olive feather bases variably visible, lower back olive and often black-barred, rump and uppertail-coverts black narrowly fringed whitish; wing-coverts mainly red, olive bases and inner webs; dark brown flight-feathers edged olive, outer edges of secondaries dark red; uppertail black; lower throat

and breast black with whitish and red feather edges, appearing scalloped, belly to undertail-coverts golden or golden-buff, usually a few black bar-like spots on upper flanks (sometimes extending farther down); underwing with at least some yellow; undertail blackish, yellow at base; in worn plumage, when brighter feather tips lost, plumage blacker on crown, more olive on upperparts, solidly black on throat and breast; shortish to fairly long bill broad-based, culmen curved, blackish; iris red-brown to brown; legs grey or brown-grey. Female lacks red on malar and crown, which are instead solid black. Juvenile duller than adult, mottled blackish, olive and dull red above, with breast all blackish, belly more brownish-buff, male with a few narrow red tips on crown. Race *meridae* is very like nominate, but bill shorter, wing on average longer; *quindiana* also much as nominate, but female has some red in crown; *brevirostris* has more black on forehead of male, paler yellow belly, more spots on flanks; *atriceps* is distinctive, with noticeably shorter bill, both sexes have black forehead and crown, olive-tinted ear-coverts, darker more bronzy-olive upperparts, little or no red in flight-feathers, paler ground colour below, breast feathers with no red tips, bar-like spotting tends to reach farther down on flanks. Voice. Sharp, upward-inflected "kawip" or "kre-ép", sometimes in short series, and loud rolling "chrrr-r-r-r", like *Colaptes*; also "kick-kick-kick-kick-kick-kick" and fast repeated "wik" as long-distance calls; does not call often. Both sexes drum, described as slow, or as fast short bursts.

**Habitat.** Tall humid and wet montane forests, especially mossy and epiphyte-rich rainforest and cloudforest, also forest edge, clearings with some trees, dry cloudforest; also dwarf forest at timberline, venturing into adjacent páramo as well. Occurs at 950-3700 m in Venezuela, 1800-3200 m in Colombia, mostly 1900-3300 m in Ecuador, and to 3700 m in Peru; locally in smaller numbers down to 700 m.

**Food and Feeding.** Ants and their brood, beetle larvae, occasional spiders and millipedes (Diplopoda); some fruit also consumed. Forages alone, in pairs or in family groups, and often joins mixed-species flocks; quiet and inconspicuous, moves slowly. Forages at practically all levels, mostly high; intermittently descends to ground to search for ants, or to feed at *Puya* and *Espletia* flowers. Inspects surfaces of thicker branches overgrown with moss and epiphytes, pays particular attention to bases of epiphytes and leaves. Often feeds in open, also in dense vegetation. Probes, gleans and pecks; hammering not a typical technique.

**Breeding.** Recorded in Feb-Mar in Colombia and Jun-Nov in Peru. No other details documented.

**Movements.** Resident. Presumably altitudinal movements may occur sometimes.

**Status and Conservation.** Not globally threatened. Fairly common. Uncommon to fairly common and widespread in Ecuador; fairly common in Peru. Unobtrusive behaviour suggests that it is perhaps overlooked. Occurs in Paschoa Forest Reserve and Podocarpus National Park (Ecuador) and Machu Picchu Historical Sanctuary (Peru); observed along Pico Humboldt Trail (Venezuela). Ability to survive in partially deforested areas and its rather frequent occurrence at trees in more open areas suggests that it is unlikely to become threatened in the near future.

**Bibliography.** Angehr & Auca (1997), Bloch *et al.* (1991), Butler (1979), Clements & Shany (2001), Cresswell, Hughes *et al.* (1999), Cresswell, Mellanby *et al.* (1999), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Hornbuckle (1999), Kirwan & Marlow (1996), Meyer de Schauensee & Phelps (1978), Moynihan (1979), Parker, Parker & Plenge (1982), Parker, Schulerberg *et al.* (1985), Poulsen (1996), Remsen (1985), Remsen & Traylor (1989), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely *et al.* (1998), Salaman (1994), Short (1985b), Stotz *et al.* (1996), Varty *et al.* (1986), Vélaz & Velázquez (1998), Walker (2001), Williams & Tobias (1994), Zimmer (1930).

flight-feathers barred yellowish, olive-yellow shafts often forming paler panel; uppertail dark brown, central feathers and outer web of outermost barred pale; underparts below breast pale yellow with black bars, more as arrowhead marks on flanks and undertail-coverts, belly more weakly marked; underwing yellow, primary coverts barred darker; undertail brown, yellower at base, barred whitish-yellow; medium-long bill pointed, culmen curved, narrow across nostrils, black, paler base; iris brown or chestnut-brown; legs green-grey. Female lacks red on forehead and crown side, has malar region blackish, not red.

Juvenile duller and darker-faced than adult, but top of head often wholly red with dark bars, more diffusely barred above and below, malar mixed red and black or, perhaps only female, all black. Race *peruvianus* differs from nominate in smaller size, shorter bill, paler and more barred upperparts, pale-edged wing-coverts, paler and less barred below. Voice. Short repeated "peah" and "chyp", mainly in alarm; loud clear "wic" in long series, similar to but not so long as that of *C. auratus*.

**Habitat.** Arid to semi-arid areas in dry cloudforest, montane scrub with large cacti, desert scrub, and wooded areas; also in riparian vegetation, irrigated areas, orchards, plantations and gardens. Locally above main tree-line into *Polylepis* woodland. At 500-2800 m, occasionally to 3400 m on W Andean slopes, to 4000 m in Cordillera Blanca (Ancash); at 1700-4300 m around Marañón Valley.

**Food and Feeding.** Ants and their larvae and pupae. Usually singly or in pairs. Essentially arboreal, but also forages near or on ground, often among bushes. Recorded techniques are gleaning and probing, including into soil, and occasional pecking.

**Breeding.** Probably Jun-Jul, and Sept (Marañón Valley). Nest-hole excavated in tree or telephone pole (*atricollis*), or in large cactus (*peruvianus*). No other details available.

**Movements.** Resident. Presumably some altitudinal movements may sometimes occur.

**Status and Conservation.** Not globally threatened. Uncommon generally; locally somewhat more common. A little-known scrubland woodpecker restricted to Peruvian Andes. Observed regularly at c. 2500 m along Santa Eulalia road, above Lima, and recorded along Trujillo-Chiclayo Circuit in NW and on dry slopes above Balsas.

**Bibliography.** Clements & Shany (2001), Fjeldså & Krabbe (1990), González & Málaga (1997), Johnson (1972), Koepeke (1961, 1970), Meyer de Schauensee (1982), Olrog (1968), Parker *et al.* (1982), Stotz *et al.* (1996), Zimmer (1930).

## 146. Spot-breasted Woodpecker

### *Colaptes punctigula*

French: Pic de Cayenne German: Tüpfelbrustspecht

Spanish: Carpintero Moteado

Other common names: Spot-breasted Flicker

**Taxonomy.** *Picus punctigula* Boddaert, 1783, Cayenne.

Sometimes placed in a separate genus *Chrysophilus* with the other "forest flickers" *C. atricollis* and *C. melanochloros*. May form a superspecies with latter. Other named races are *lutescens* (E Darién), not reliably distinct from *ujhelyii*; "notatus" (Colombia), known only from unique type, possibly an aberrant *punctipictus*; and *speciosus* (E Peru) and *rubidipictus* (NE Brazil N of Amazon), both considered indistinguishable from *guttatus*. Six subspecies recognized.

#### Subspecies and Distribution.

*C. p. striatigularis* (Chapman, 1914) - WC Colombia.

*C. p. ujhelyii* (Madarász, 1912) - E Panama (E Darién) and N Colombia.

*C. p. zuliae* (Cory, 1915) - NW Venezuela.

*C. p. punctipictus* (Cabanis & Heine, 1863) - E Colombia and most of Venezuela (except NW).

*C. p. punctigula* (Boddaert, 1783) - the Guianas.

*C. p. guttatus* (Spix, 1824) - Amazonia from E Ecuador and E Peru E to NE Brazil (Pará), S to NW Bolivia and N Mato Grosso.

**Descriptive notes.** c. 18-21 cm; 50-70 g (*punctigula*), 75-79 g (*guttatus* from upper Amazonia). Male has black forehead and forecrown, red hindcrown and nape (exceptionally, red extends forwards along crown side, even over entire crown); white lores, area above and below eye and ear-coverts, red malar stripe with black feather bases; black chin and throat spotted white; upperparts, including wing-coverts and tertials, bronze-green with brownish-black bars, rump paler and less barred; brown flight-feathers indistinctly barred paler, yellow shafts often forming panel; uppertail brown, outer feathers strongly barred green to yellow,

central pair sometimes also with weak bars; dull yellow-olive below, upper breast often tinged reddish, becoming paler on belly, breast with fine black spots, flanks more sparsely spotted, yellowish undertail-coverts spotted black; underwing pale yellowish; undertail yellow-brown, barred brown; short bill pointed, culmen curved, narrow across nostrils, blackish; iris rufous-brown; legs greenish-grey to yellow-tinged. Distinguished from *C. melanochloros* by much smaller size, less green appearance, less barred and variegated upperparts and wings. Female lacks red malar, always has red restricted to rear crown and nape. Juvenile as adult, but duller and greener above, duller below with larger spots, male with some red in malar. Races differ from nominate in larger size, plumage tones and markings: *striatigularis* has throat very white with few black streaks, strong reddish tinge on rump and breast, spotting below fairly heavy; *ujhelyii* has throat as previous, is very bright, with red to orange on breast, barring above much reduced, male's crown sometimes almost entirely red; *zuliae* is almost as small as nominate, dull above, with relatively little black on throat, breast spots sparse; *punctipictus* is greener above, lacking bronzy tone, dull below with spots fewer and small, throat generally black with large white spots; *guttatus* has rump less contrasting, throat black with large white spots, very olive on breast, relatively heavy spotting below, variable. Voice. Rather high-pitched weak and nasal "wha" or "kah" or "keeh" in series of 8-12 notes, first and second slightly lower; "peek" notes in series when alarmed; whistled "whew" during courtship or in agonistic encounters; also series of "ta-wick" or "week-a" associated with visual displays, likewise or in response to calls of other individuals typically fast series of "wick" notes sometimes commencing

## Genus COLAPTES Vigors, 1826

## 145. Black-necked Woodpecker

### *Colaptes atricollis*

French: Pic à cou noir

German: Graustirnspecht

Spanish: Carpintero Peruano

Other common names: Black-necked Flicker

**Taxonomy.** *Chrysopicops atricollis* Malherbe, 1850, Peru.

Sometimes placed with *C. punctigula* and *C. melanochloros* in a separate genus *Chrysophilus*, the so-called "forest flickers". Two subspecies recognized.

#### Subspecies and Distribution.

*C. a. atricollis* (Malherbe, 1850) - W slope of Peruvian Andes from La Libertad and Ancash S to W Arequipa.

*C. a. peruvianus* (Reichenbach, 1854) - Marañón Valley S on E slope to W Huánuco.

**Descriptive notes.** 26-27 cm; 73-90 g (*atricollis*). Male has dark grey forehead to hindcrown, feathers tipped red on forehead and crown side, occasionally over entire crown, red hindcrown and upper nape; yellowish-white lores and line above eye, ear-coverts similar but often tinged buffish-olive; olive-grey neck side barred black; red malar band with black feather bases; black chin, throat and upper breast; hindneck and upperparts, including wing-coverts and tertials, bronze-green with narrow blackish bars, rump and uppertail-coverts paler and with paler bars; dark brown

with “ka-wick” elements; low soft “pee-ya” calls at intimate meetings, e.g. during change-over at nest.

**Habitat.** Wide array of wooded and open habitats: occurs in rainforest, deciduous and gallery forest, *várzea* forest, riparian woodland, second growth, open woodland, mangroves, swamp edges, *llanos*, forest edge, open terrain with large trees, scrub, clearings, moriche palm groves, coffee plantations, other cultivations with sufficient trees, palm savanna. Commonly prefers sparsely wooded regions, generally not a typical forest species. Primarily in humid lowlands; to 600 m in Venezuela, to 1500 m in Colombia, to 1200 m and locally 1600 m in Ecuador, and to 900 m in Peru.

**Food and Feeding.** Ants and their brood. Lives in pairs or family groups. Arboreal foraging takes place at medium heights and lower; also descends to ground among scattered trees to forage at anthills. In trees, gleaning, probing and occasional light pecking predominant techniques. On ground, probes into soil and sweeps away litter.

**Breeding.** Oct-May in Colombia, Jun-Aug in the Guianas, Apr-Oct in Amazonian Basin, and Feb-Sept in Peru. In close encounters, displays with head-swinging and head-bobbing, and spread tail. Nest-hole excavated by both sexes in live or dead tree, sometimes in fence post. No information on clutch size or on incubation and fledging periods.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare in Panama; fairly common in rest of range. Occurs in Laguna de Sonso Reserve (Colombia) and in Manu National Park (Peru). Adaptable species; its preference for more open woodland means that it does not suffer too much from effects of clearance. Indeed, appears to have increased in some regions as a result of deforestation; in Ecuador, has spread upwards on Andean slopes following creation of clearings. No known threats.

**Bibliography.** Allen (1995), Anon. (1998b), Borges *et al.* (2001), Clements & Shany (2001), Donahue (1994), Fjeldså & Mayer (1996), Friedmann (1948), Friedmann & Smith (1950, 1955), Guilherme (2001), Haverschmidt & Mees (1994), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Robinson (1997), Robinson & Terborgh (1997), Short (1985b), Sick (1993), da Silva *et al.* (1990), Snyder (1966), Stotz *et al.* (1996), Strewé (2000a), Terborgh *et al.* (1984), Tostain *et al.* (1992), Vélez & Velázquez (1998), Wetmore (1968a).

147. Green-barred Woodpecker

*Colaptes melanochloros*

**French:** Pic vert et noir      **German:** Grünbindenspecht      **Spanish:** Carpintero Real  
**Other common names:** Green-barred Flicker; Golden-breasted Woodpecker (*melanolaimus* group)

**Taxonomy.** *Picus melanochloros* J. F. Gmelin, 1788, Cayenne; error = Rio de Janeiro, Brazil. Sometimes placed in a separate genus *Chrysomitris* with the other “forest flickers” *C. atricollis* and *C. punctigula*. May form a superspecies with latter. Partly terrestrial group of S races inhabiting *pampas* and Chaco woodland sometimes regarded as forming a separate species comprising the taxa *melanolaimus*, *nigroviridis* and *leucofrenatus*, distinct from the more arboreal nominate race and *nattereri*. The last two intergrade widely, the others to a lesser extent, and the two groups interbreed along the R Paraná and R Uruguay. Additional named races *mariae* (Marajó I, NE Brazil), *fluvilumbis* (Bahia), *perplexus* (E Argentina) and *patagonicus* (WC Argentina) are all considered insufficiently differentiated to warrant recognition. Five subspecies recognized.

**Subspecies and Distribution.**

*C. m. nattereri* (Malherbe, 1845) - NE & SC Brazil S to E Bolivia (Santa Cruz).  
*C. m. melanochloros* (J. F. Gmelin, 1788) - S & SE Brazil, SE Paraguay, NE Argentina (E Formosa, Misiones) and Uruguay.  
*C. m. melanolaimus* (Malherbe, 1857) - arid upland valleys in C & S Bolivia.  
*C. m. nigroviridis* (C. H. B. Grant, 1911) - S Bolivia, W Paraguay, N & E Argentina (S to Córdoba and Buenos Aires) and W Uruguay.  
*C. m. leucofrenatus* Leybold, 1873 - NW & WC Argentina (S to Neuquén, W Río Negro).

**Descriptive notes.** c. 27-30 cm; 104-150 g (smaller races), 154-178 g (*leucofrenatus*). Male has black forehead and forecrown, red hindcrown and nape, whitish lores, cheeks and ear-coverts, ear-coverts strongly tinged olive; red malar stripe with black feather bases; whitish-green chin and throat streaked black; upperparts, including wing-coverts and tertials, yellowish-green, barred dark brown, rump paler and less barred, uppertail-coverts buff with black bars; greenish-brown flight-

feathers narrowly barred paler, olive shafts; uppertail black, at least outer feathers barred pale; pale green below, usually darker and brighter on breast, with prominent black spots, often tending towards bars on flanks, spots becoming smaller or absent on belly; yellowish-white underwing, primary coverts sometimes spotted; black undertail barred yellowish; fairly long bill pointed, culmen curved, narrow across nostrils, black; iris brown to chestnut-brown; legs grey, usually tinged greenish or yellow. Female has proportionately longer tail than male, has malar mostly black with white streaks, without red. Juvenile duller than

adult, with broader barring above, markings below more bar-like. Races differ in size and colour tones, S group living in *pampas* and Chaco being bigger and browner: *nattereri* resembles nominate, but smaller, shorter-billed, more yellow, spots below often very small or streak-like; *melanolaimus* is longer-billed, fairly green in tone, with rump less marked, tail less barred, golden tinge on breast but whiter below, black patch on throat side; *nigroviridis* is like previous, but tends to more greenish coloration above, tail strongly barred, less golden on breast, less black on throat side, spots below larger; *leucofrenatus* is large, browner above, even golden-brown, with white rump, whitish bars and edges, breast golden to orange, flanks strongly barred, large spots or arrow-head marks below. VOICE. Call “kwiek-kwik-kwik”, similar to that of *C. campestris*; also “peah” or screechy “wheéo”, and “krrew”, “pikwarr”; “peek” as alarm, also given singly; also “ta-wick” or “ker wick” and variations, much as those of *C. auratus* or perhaps slightly sharper, and long series. Both sexes drum, rolls slower than those of *C. auratus*.

**Habitat.** Variety of habitats, from lowland forest to Andean desert scrub. Nominate race inhabits subtropical humid forest and transitional forest, especially when mixed with bamboo. Race *melanolaimus* generally in woodland, savanna, open country and arid bushland; *nattereri* in savanna and *caatinga*. Lowlands and foothills; to 3000 m in Bolivia (*melanolaimus*).

**Food and Feeding.** Almost exclusively ants and their brood; genera *Camponotus*, *Crematogaster*, *Paracryptocerus* and others identified. Spiders also recorded. Cactus fruits and berries taken, also sap. Mostly singly, sometimes in pairs; joins groups of the larger and more wary *C. campestris* to feed on ants on ground. Forages regularly in lower and middle sections of trees and palms, in low bushes, and bamboo; hops through crown of trees, also hangs on underside of branches. Probing and gleaning are main techniques in trees. Breaks through surface with a few pecks; if prey detected, considerable time may be spent in removing it with tongue. Also forages on ground, especially “*melanolaimus* group”; progresses in long bounds or moves in short hops.

**Breeding.** From Aug-Sept to Jan in S; earlier in N. Display with wing flicks, spread tail, swinging and bobbing head-and-body movements; calls for prolonged periods from top of tree or palm. Nest-hole made in dead tree or dead stump, palm, cactus, or telephone pole, at height of 2-6 m. Clutch 4 eggs; both parents incubate, and both also feed chicks, by regurgitation; incubation and fledging periods not documented.

**Movements.** At least partly migratory in extreme S and in Córdoba highlands of C Argentina; some move N to Gran Chaco region (e.g. Santiago del Estero) after breeding.

**Status and Conservation.** Not globally threatened. Common in most of range. Occurs in numerous protected areas, including Itatiaia, Serra do Cipó and Brasília National Parks (Brazil), Ybicui National Park (Paraguay), Iguazú National Park and Urugua-í, La Araucaria and Chancani Provincial Parks (Argentina). Recorded regularly on Montevideo-Chuy-Minas Circuit (Uruguay). No known threats.

## 148. Northern Flicker

*Colaptes auratus*

**French:** Pic flamboyant      **German:** Goldspecht      **Spanish:** Carpintero Escapulario  
**Other common names:** Common Flicker; Yellow-shafted Flicker (*auratus* group); Red-shafted Flicker (*cafer* group); Cuban Flicker (*chrysocaulus* group); Guatemalan Flicker (*mexicanoides* group)

**Taxonomy.** *Cuculus auratus* Linnaeus, 1758, South Carolina. Forms a superspecies with *C. chrysoides*; sometimes treated as conspecific but, although SW populations not significantly different genetically from that species, hybridization is very limited (in C & S Arizona), with moderate ecological separation too, and the two are better regarded as allopecies. Races commonly divided into four geographical groups, each considered a separate species in the past: "*auratus* group" (which includes *luteus*) in N & E North America, with yellow flight-feather shafts; "*cafer* group" (also including *collaris*, *mexicanus*, *nanus* and extinct *rufipileus*) in W North America and Mexico, with red shafts; "*mexicanoides* group" in highlands from S Mexico to Nicaragua; and geographically isolated "*chrysocaulus* group" (with *gundlachi*) in Cuba and Grand Cayman. First two groups interbreed in extensive and long since stable hybrid zone from Alaska through the Great Plains, where relatively few individuals are typical of one form or the other, and non-assortative mating is common. Relationships among groups and individual races complex, poorly understood; also, considerable individual variation occurs, and races interbreed wherever they meet; further research and revision needed. Additional described races, considered to represent intergrades or otherwise inadequately differentiated, include *borealis* (NW to NC North America), *sedentarius* (Santa Cruz I, California), *martirensis* (San Pedro Mártir Mts. in NW Baja California) and *pinicolus* (highlands of El Salvador to N Nicaragua). Race *rufipileus* (Guadalupe I, off W Baja California) is extinct. Nine extant subspecies recognized.

**Subspecies and Distribution.**

*C. a. luteus* Bangs, 1898 - C Alaska E across Canada to S Labrador and Newfoundland, and S to Montana and NE USA.

*C. a. auratus* (Linnaeus, 1758) - SE USA.

*C. a. cafer* (J. F. Gmelin, 1788) - S Alaska and British Columbia S to N California.

*C. a. collaris* Vigors, 1829 - SW USA S to NW Baja California and W Mexico (S to about Durango).

*C. a. mexicanus* Swainson, 1827 - Durango E across Mexican Plateau to San Luis Potosí and S to Oaxaca.

*C. a. nanus* Griscom, 1934 - W Texas S to NE Mexico.

*C. a. mexicanoides* Lafresnaye, 1844 - highlands from S Mexico (Chiapas) to Nicaragua.

*C. a. chrysocaulus* Gundlach, 1858 - Cuba.

*C. a. gundlachi* Cory, 1886 - Grand Cayman I.

**Descriptive notes.** c. 30-35 cm; 106-164 g (*auratus*), 121-167 g (*collaris*), 105-126 g (*nanus*), 88 g (*gundlachi*). Male has grey forehead to hindneck and rear neck side, patch of deep red on lower nape extending to side of nape (forming V shape), black malar stripe; rest of head and down to upper breast cinnamon, usually darker around eye, often more greyish on rear ear-coverts; brown upperparts barred blackish, rump unbarred white (occasionally variable black marks), uppertail-coverts white with black subterminal marks; dark brown flight-feathers narrowly barred pale brown, shafts yellow; uppertail blackish-brown, initially tipped and edged buffy, outermost feather with hint of pale bars on outer web, centre of shafts yellow; broad black crescent across centre of breast; rest of underparts white with pale buffish-yellow wash, rounded black spots becoming more crescentic on flanks, more bar-like or wedge-shaped on undertail-coverts; yellowish underwing, darker tip and trailing edge, spots or bars on primary coverts; undertail yellow, tip black; fairly long bill pointed, culmen curved, narrow across nostrils, black or slaty; iris deep brown; legs grey, tinged green. Distinguished from *C. chrysoides* by larger size, head pattern, yellow shafts. Female is slightly smaller than male, lacks black malar, has breast crescent slightly less deep. Juvenile as adult, but often more greyish colour on head, crown sometimes barred, usually black loreal patch, dark bars above much broader, tail-coverts with more black, breast crescent smaller, spots larger, underwing duller yellow, male usually with dull red on crown and less distinct black malar, female head even less marked. Races differ considerably in size, plumage coloration and markings: *luteus* resembles nominate but somewhat larger; *cafer* has grey face and throat to breast, red malar, no red nape patch, salmon-pink shafts, underwing and undertail, female sometimes with cinnamon malar; *collaris* is like previous but paler, female with moderate rufous malar; *mexicanus* is smaller and browner than last; *nanus* is smaller still, and greyer; extinct *rufipileus* had short wing and tail, rather long bill, rufous crown; *mexicanoides* is large, bright, with rusty forehead to hindneck, grey face and breast, male's red malar mixed with black, above strongly barred buff, grey-brown and blackish, breast patch deeper and less crescent-shaped, spots below often larger, shafts and undersurfaces of wings and tail orange-red, female with pale cinnamon-brown malar finely streaked darker; *chrysocaulus* has proportionately longer tail, head pattern as nominate, upperparts more olive above, even occasionally tinged reddish, rump more heavily barred, tail more barred, breast crescent deeper, spots below broader, yellow of shafts and undersurfaces more golden; *gundlachi* is very like previous but smaller, shorter-tailed, with smaller red nape patch. **VOICE.** Common call a descending "peah" or "klee-yer"; typical is a long series of up to c. 70 "whit" notes, given throughout breeding season to autumn; "wicka" and variants, e.g. "ew-i", "cha-week-a", "wee-cha", "wik-up" and suchlike, varying in intensity, during aggressive encounters or courtship; soft "wee-tew" when approaching mate, or "wa-wa-wa" in flight or when mildly disturbed; low hissing by young nestlings, louder and variable later. Drumrolls not very loud, slower than similar rolls of *Picoides villosus*, but uniform rhythm.

**Habitat.** Broad range of habitats giving access to open ground: mainly open areas and forest edge. Primarily open forest, younger (2-6 years) clear-cuts, burnt areas, farmland, pastures and residential areas in main part of range; parkland with e.g. aspen (*Populus*) and lodgepole pine (*Pinus contorta*), ponderosa pine (*P. ponderosa*) forest, alpine meadow edge, riparian woodland and forest edge are typical habitats in N; occurs in woodland along streams in the Great Plains, and in W common in quaking aspen (*Populus tremuloides*) stands. Inhabits the oak (*Quercus*) and pine-oak zone in Mexico; also second growth in cloudforest belt in Guatemala and Honduras. Also man-

groves in Caribbean region. Wide variety of habitats used in winter, too; in temperate zone, denser habitats visited at that season than at other seasons. Breeds from sea-level to 2100 m in N; at 750-3300 m, occasionally to 4000 m, in Mexico; occurs from c. 600 m, mostly above 900 m, to 3200 m in Guatemala and Honduras.

**Food and Feeding.** Chiefly ants and their brood, also other insects, spiders, occasionally molluscs and crustaceans; fruits, berries and seeds also important, especially in winter. Ants form up to c. 75% of diet, sometimes more, and include especially *Formica*, *Lasius*, *Camponotus*, *Myrmica*, *Crematogaster*, but at least 6 other genera commonly recorded. Other insects include termites (Isoptera), caterpillars, beetles and their larvae, wasps, Orthoptera, aphids. Fruits and berries of wide variety of plants taken, e.g. several species of *Rhus* and especially poison ivy (*R. radicans*), dogwood (*Cornus florida*), hackberry (*Celtis occidentalis*), cherries (*Prunus*), black gum (*Nyssa*), *Rubus*, *Ribes* and many others, as well as seeds, acorns and other kinds of nut-like crops. Visits feeders. Forages singly, in pairs or in family groups; also in flocks of up to c. 15 birds during migration. Feeds commonly on the ground, on lawns, road shoulders, forest floor and similar sites; trees and bushes also visited for harvesting fruits and other plant matter; more arboreal in Cuba (*chrysocaulus*) and Grand Cayman (*gundlachi*). On ground progresses by hopping; sweeps away litter, digs into ant nests with the bill; berries also collected on ground. In arboreal foraging, dead trees or broken ends of dead branches are important sites (about 75% of observed cases); moves in manner of tit (Paridae) among the twigs, frequently perches crosswise. Main techniques gleaning and probing; most prey secured with the tongue. Also catches insects on the wing.

**Breeding.** Apr-Jul; from Jun in N and from Feb-Mar in S; rarely, 2 broods reared in a season. Monogamous, apparently pairs for life. Displays characterized by steep upward-pointing of bill with tail-spreading, bill describing circles or figures-of-eight, bobbing movements with wings raised, also tail spread and twisted to reveal underside. Nest excavated by both sexes, taking 5-20 days, male about twice as active as female, in dead tree or in dead part of live tree, usually close to distal end of a stub, at variable height, often below 3 m but to 27 m, mostly c. 6-12 m in forests; average entrance diameter 7-9 cm, cavity depth 33-40 cm; very often, however, old cavity selected, or wide variety of other sites (e.g. fence post, utility pole, clothesline pole, marine breakwater pilings, soft cliff, haystack or suitable structure on building), or old burrow of other bird, or nestbox used; territory vigorously defended. Clutch 3-12 eggs, mostly 4-9, average of 411 clutches was 6-5 eggs, larger clutches of up to 17 eggs probably product of more than 1 female; both sexes incubate, male taking greater share, period 11-12 days; chicks fed by regurgitation, male seeming to feed at higher rate than female, feeding and nest sanitation reduced towards end of nestling period; fledging period 25-28 days; young remain with parents for variable period, fed by them for up to c. 15-20 days. Hatching success 1-10 chicks, mostly 5-7, on average 1-1 fewer than eggs produced; holes often usurped by Common Starlings (*Sturnus vulgaris*). First breeding at 1 year, some females not until 2 years. Maximum recorded longevity 9 years 2 months.

**Movements.** Resident in C & S of range. Canadian populations migratory, as indeed are many of those breeding N of California, Oklahoma and Georgia; autumn migration begins towards end Aug and lasts to late Oct or Nov, with peak in Sept; migrates by day, in sometimes large flocks, low over ground. Winter concentrations in USA from SW states through Texas to Florida; *auratus* group winters S to N Mexico (Sonora E to Tamaulipas), where present Oct-Mar. N populations arrive back on breeding grounds from early Mar to May.

**Status and Conservation.** Not globally threatened. Common throughout most of range, locally very common to abundant in Canada and USA; common to fairly common in Mexico. In Caribbean, fairly common on Grand Cayman (*gundlachi*); generally uncommon and local in Cuba, where more arboreal race *chrysocaulus* is decreasing, chiefly as a result of deforestation. Breeding densities very variable, locally as high as 4-8 pairs/10 ha in North America; 1-8 pairs/40 ha in oak and conifer woodland. Decline recorded in Canada and USA, with reduction of 52% in *auratus* group and 19% in *cafer* group since mid-1960's. Likely cause of decline is loss of suitable nest-sites following removal of snags and dead tree limbs; competition with other hole-nesters, including other woodpeckers and introduced Common Starlings, also probably significant, at least locally. In early part of 20th century, migrants shot in large numbers, particularly on E coast at Cape May (New Jersey), with hundreds killed in a single morning; such practices now illegal, and probably only very few shot. Nevertheless, can cause problems in the human environment, mainly through excavating in unusual places; a notorious instance, in 1995, involved two individuals which excavated c. 200 holes in the insulation of fuel tanks of the Space Shuttle on its launch pad at the Kennedy Space Centre, resulting in costs totalling more than US\$1,000,000. Race *rufipileus* of Guadalupe I extinct: last record in 1906, when remaining population estimated at c. 40 birds (this total perhaps included 12 birds collected during this same visit); extinction almost certainly due to habitat destruction by goats, compounded by predation by cats.

## 149. Gilded Flicker

*Colaptes chrysoides*

**French:** Pic chrysoidé      **German:** Wüstengoldspecht      **Spanish:** Carpintero de California

**Taxonomy.** *Geopicus (Colaptes) chrysoides*, Malherbe, 1852, Cape San Lucas, Baja California. Forms a superspecies with *C. auratus*. Genetically is not significantly divergent from SW "cafer group" of that species, and treated as conspecific by some authors, but separated to a reasonable extent by habitat preferences, with limited hybridization; considered better treated as allopecies. Races intergrade clinally. Four subspecies recognized.

**Subspecies and Distribution.**

*C. c. brunnescens* Anthony, 1895 - N & C Baja California.

*C. c. chrysoides* (Malherbe, 1852) - S Baja California.

*C. c. mearnsi* Ridgway, 1911 - extreme SE California (Colorado Valley) and S & C Arizona S in desert to NW Mexico (N Sonora).

*C. c. tenebrosus* van Rossem, 1930 - N Sonora to N Sinaloa.

**Descriptive notes.** c. 26-30 cm; 92-129 g (*mearnsi*). Male has rusty to rufous-yellow forehead to hindneck, red malar, rest of head down to upper breast grey; pale brownish upperparts heavily barred blackish, rump white, uppertail-coverts white with black bars, median wing-coverts tipped white; dark brown flight-feathers narrowly barred pale brown, yellow shafts; uppertail blackish-brown, outermost feather with faint pale lines on outer web, shafts yellow; broad, deep black breast crescent, otherwise white below with rounded black spots, these becoming more crescent-shaped on flanks, more bar-like on undertail-

coverts; yellow underwing, darker tip and trailing edge; undertail yellow, broad black tip; medium-long bill pointed, culmen slightly curved, narrow across nostrils, dark grey to black; iris deep brown; legs grey. Female lacks red malar, may have faint pale rusty mark. Juvenile has broader dark bars above, smaller breast crescent, bigger spots below, duller yellow on underwing, male usually with red tinge on crown and malar, female head plainer. Races differ little from nominate: *brunnescens* is browner above, moderately barred; *mearnsi* is largest, rather pale; *tenebrosus* is smaller, darker, heavily barred. Voice. Descending "peah" or "klee-yeer", long series of "whit" notes in spring to autumn, "wicka" and variants, also other vocalizations, all much as for *C. auratus* but voice on average slightly higher. Drumrolls soft.

**Habitat.** Arid scrub and desert with large cacti and yucca (*Yucca*) plants, and dry riverine woodland with cottonwoods (*Populus*) and willows (*Salix*); from sea-level to 250 m in Baja California, to about 900 m farther E.

**Food and Feeding.** Ants and their brood, and other insects. Also fruits, e.g. of cactus, and berries; also nuts, including pecan (*Carya*) and walnut (*Juglans*). Forages singly or in pairs, frequently on ground. Visits feeders. Main techniques probing and gleaning.

**Breeding.** Laying Feb-Jun. Nest most frequently excavated in large cactus, particularly saguaro cactus (*Carnegiea gigantea*), at 3-12 m, less commonly in cottonwood or willow tree or in stub at 1.5-8 m; entrance hole averages c. 7 cm tall, c. 8.5 cm across, mean cavity depth 36-38 cm. Clutch usually 3-5 eggs; incubation c. 11 days; fledging period c. 24-25 days.

**Movements.** Resident; wanderers recorded N to SW Utah.

**Status and Conservation.** Not globally threatened. Common. Stable or increasing in USA, with average increase of 8% annually since 1968. In Mexico, conversion of cactus deserts to irrigated farmland has probably resulted in a decline in this species' numbers, but no data available. Strong competition for nest-sites likely from introduced Common Starlings (*Sturnus vulgaris*), which have successfully conquered the arid habitats of the SW; one study, however, reported that this woodpecker suffered far less in this respect than did *Melanerpes uropygialis*. Occasional conflict with man possible, as it can cause some damage in commercial plantations of pecans and walnuts.

**Bibliography.** Anon. (1998b), Baicich & Harrison (1997), Bent (1939), Braun (1969), Brush *et al.* (1990), DeBenedictis (1997), Friedmann *et al.* (1957), Howell & Webb (1995), Hunter (1984), Johnson (1969), Kaufman (1996), Koenig (1984a), McAuliffe & Hendricks (1988), Price *et al.* (1995), Root (1988), Small (1994), Test (1945), Zwartjes & Nordell (1998).

## 150. Fernandina's Flicker

### *Colaptes fernandinae*

**French:** Pic de Fernandina

**German:** Kubaspecht

**Spanish:** Carpintero Churroso

**Other common names:** Cuban Flicker/Woodpecker

**Taxonomy.** *Colaptes Fernandinae* Vigors, 1827, near Habana, Cuba.

Formerly separated in monotypic genus *Nesocoeles*. Monotypic.

**Distribution.** Cuba (distribution now very patchy).

**Descriptive notes.** c. 30 cm. Male has buff-cinnamon forehead to nape finely streaked black, occasionally hint of red on nape; whitish-buff lores and narrow line above and below eye, buffish-yellow ear-coverts more cinnamon at rear; black malar stripe, sometimes mixed with red; whitish chin and throat heavily streaked black, black spots on lower throat and throat sides; pale yellow to buffish-yellow upperparts, including wing-coverts and tertials, densely barred blackish-brown, rump and uppertail-coverts paler with bars narrower; dark brown flight-feathers narrowly barred yellow-buff; uppertail brownish-black, all feathers

narrowly barred buff-yellow; pale yellowish-buff below with dark brown bars, markings weaker on belly; yellow underwing rather obscurely barred, yellow undertail; long bill pointed, curved, narrow across nostrils, black; iris deep brown; legs dark grey. Female differs from male in having black malar heavily streaked white, never any hint of red on nape. Juvenile duller and browner, with less barring above, broader markings below. Voice. Loud "pic" series, slower and lower-pitched than *C. auratus*; also typical "wicka" series, loud, nasal "ch-ch-ch" during breeding.

**Habitat.** Prefers rather open woodland and pasture with palms, in both dry and wetter habitats; occurs to lesser extent also in denser woodland. Closely associated with palm trees, especially *Sabal parviflora*.

**Food and Feeding.** Insects, worms, grubs, seeds. Forages singly, also in pairs when breeding. Often feeds on ground, more so than local race *chrysocaulatus* of *C. auratus*; visits lawns and dusty tracks. Probes into the soil and under leaves.

**Breeding.** Mar-Jun. Solitary; locally (Zapata Swamp, in Matanzas) loosely colonial. Frequent aerial chases in courtship. Nest excavated at relatively low height, c. 3-6 m, in dead or live palm, especially *Sabal parviflora*, or dead tree, entrance hole averages c. 9 cm across, c. 8.5 cm tall, cavity depth 60 cm; old hole, even of another species, quite often reused. Clutch 3-5 eggs; incubation period c. 18 days; fledging period c. 22 days.

**Movements.** Resident.

**Status and Conservation.** ENDANGERED. Population extremely small and fragmented; maximum total estimated at 400 pairs, probably only 300, possibly even fewer. By far largest population is at Zapata Swamp, in Matanzas, where perhaps 120 pairs (occasionally in loose colonies). Was formerly widespread in Cuba, although seems never to have been very common. Declined during 20th century, and now restricted to a few small localized populations in three provinces: Pinar del Río in W Cuba, and Matanzas and Camagüey in C part of island. May still survive in several other provinces; recent record from a new locality in SE Cuba (La Platica, in Sierra Maestra) suggests that small, undiscovered populations could exist elsewhere. Extensive habitat loss resulting from clearance of forest for agricultural purposes, as well as logging, at least partly responsible for its decline, and continue to be so, but other factors may be important. Dead palms are often shared for nesting with the Near-threatened Cuban Amazon (*Amazona leucocephala*), and are frequently pushed over by bird-trappers in order to collect parrot nestlings; the flicker then loses both its own brood of young and a good nest-site. Hurricanes, too, can have a devastating effect on dead palms. Additional pressure comes from competition with other hole-nesting birds, especially *C. auratus*, *Melanerpes superciliosus* and *Xiphidiopicus percussus*; a further potential problem is nest predation by *M. superciliosus*, although significance of this has not been assessed. Despite efforts of Cuban government to safeguard the country's wildlife, including creation of many reserves, funding has proved very difficult; Zapata Swamp an important reserve, but resources for ensuring its effective protection are totally inadequate. Conservation measures proposed include the displaying of posters in villages in areas where the species still exists, aimed at raising awareness of the plight of this rare woodpecker. Additional measures are implementation of a nestbox scheme in known nesting areas, and census of all current and former sites where it is known to have bred in order to determine its exact range and status. Detailed study of its feeding and nesting requirements also considered desirable.

**Bibliography.** Anon. (1998b), Barbour (1943), Bond (1985), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cruz (1974a), Faaborg (1985), García (1992, 1993), García & González (1985), Garrido (1985), Garrido & Kirkconnell (2000), Gotto (1997), Melián (2000), Mitchell (1998), Mitchell & Wells (1997), Mitchell *et al.* (2000), Raffaele *et al.* (1998), Rompré *et al.* (1999), Ruten (1934), Salmon (1974), Seth-Smith (1912), Short (1965b, 1971e), Stattersfield & Capper (2000), Stotz *et al.* (1996), Suárez & Arredondo (1997), Wallace (2001).

## 151. Chilean Flicker

### *Colaptes pitius*

**French:** Pic du Chili

**German:** Bänderspecht

**Spanish:** Carpintero Pitío

**Taxonomy.** *Picus Pitius* Molina, 1782, Chile.

Birds in S Argentina named as race *cachinnans* on basis of proportionately shorter tail, but differences are insignificant. Monotypic.

**Distribution.** C & S Chile (Coquimbo S to C Magallanes) and adjacent SW Argentina (Neuquén S to W Santa Cruz).

**Descriptive notes.** c. 30 cm; 100-163 g. Male has dark slate-grey forehead to nape, blacker at sides, nape rarely with hint of red; buffish lores, area around eye and ear-coverts, buffish malar region finely spotted black or black and red; buffish-white chin and throat, spotted black on lower throat; upperparts, including wing-coverts and tertials, blackish-brown with narrow white to buff-white bars, in worn plumage much browner with pale bars mostly lost; rump unmarked white or with few black spots; dark brown flight-feathers, primaries notched whitish with pale shafts, secondaries narrowly barred whitish-buff; uppertail brown-black,

outer and central feather pairs narrowly barred white; whitish below, broadly barred blackish-brown, bars tending to merge on breast, belly with smaller markings or plain; underwing yellowish, darker tip, some bars on primary coverts; undertail yellowish, obscurely barred; fairly long bill pointed, culmen curved, narrow across nostrils, black; iris yellowish; legs grey or green-grey. Female lacks black or red in malar, never shows any red on nape. Juvenile as adult, but crown blacker with narrow buff tips, more broadly barred above, more spotted below, eyes brown. Voice. Distinct repeated "pitéu"; whistled variable "kwee", singly or in series, louder and more raucous than note of *C. rupicola*; long "wic wic wic" series, higher-pitched and less clear than corresponding notes of *C. auratus*; "week-a, week-a" during encounters similarly higher.

**Habitat.** Inhabits woodland and open wooded country, including open areas within *Nothofagus* forest, forest edge, riparian woodland, tree plantations, and various types of scrubby vegetation, typically with scattered bushes. Ranges from 600 m to over 1000 m; sometimes down to sea-level, at least in winter.

**Food and Feeding.** Almost exclusively ants and their brood; other items, such as scorpions (Scorpiones) and grubs, occasionally taken. Roves about in noisy family groups, easily detected. Forages mainly on ground, but never far from trees. Hops on ground, where feeds by poking, sweeping away debris, and digging into soil; also investigates fallen logs and stumps. Rarely forages in trees, and then rather unenthusiastically; flies into trees when alarmed, and may then peck in agitated manner.

**Breeding.** Reported in Oct-Dec. Known displays are head-swinging, bobbing with tail-spreading. Nest excavated in dead tree or stub, or in bank; apparently highly territorial. Clutch 4-6 eggs; no information on incubation and fledging periods.

**Movements.** Resident; possibly nomadic to some extent.

**Status and Conservation.** Not globally threatened. Generally rather common, though few data available. Occurs in Cerro La Campana, Nahuelbuta and Vicente Pérez Rosales National Parks (Chile); recorded from Calafate (Argentina), and also at L. Peñuelas and Puerto Natales (Chile). No known threats.

**Bibliography.** Araya & Chester (1993), Canevari *et al.* (1991), Chebez *et al.* (1999), Cofré (1999), Fjeldsá & Krabbe (1990), Johnson (1967), Mazar Barnett & Pearman (2001), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Olrog (1968), de la Peña (1994), Pereyra (1950), Stotz *et al.* (1996), Vuilleumier (1985), Weimore (1926).

# 152. Andean Flicker

## *Colaptes rupicola*

French: Pic des rochers

German: Andenspecht

Spanish: Carpintero Andino

**Taxonomy.** *Colaptes rupicola* d'Orbigny, 1840, no locality = Sicasica, La Paz, Bolivia. Races interbreed in Peru. Three subspecies recognized.

### Subspecies and Distribution.

*C. r. cinereicapillus* Reichenbach, 1854 - extreme S Ecuador (SE Loja) and N Peru (Piura, Amazonas).  
*C. r. puna* Cabanis, 1883 - C & S Peru.  
*C. r. rupicola* d'Orbigny, 1840 - W, C & S Bolivia (Tarapacá) and NW Argentina (Jujuy S to Catamarca).

**Descriptive notes.** c. 32 cm; 142-204 g, female c. 5% lighter than male. Male has dark slate-grey forehead to hindneck, blacker at side, sometimes trace of red on hindneck, thin black malar stripe tipped red, rest of face including line above eye, neck side, chin and throat pale buffish-white, slightly darker on ear-coverts; upperparts, including wing-coverts and tertials, barred with brown, light brown and buffish-white, rump plain buffish-white (occasionally a few bars), uppertail-coverts white with narrow dark bars; dark brown flight-feathers narrowly barred pale buff; uppertail black, outer and central feathers thinly barred; whitish be-

low, breast washed variable orange-buff and with blackish spots or small chevrons, marks sometimes extending to neck side and flanks; undertail-coverts occasionally with short bars; underwing pale buff-yellow, darker tip and trailing edge, a few spots on primary coverts; undertail often yellowish at sides; extremely long bill pointed, culmen curved, narrow across nostrils but broad-based, black; iris pale lemon-yellow; legs yellowish-grey to greyish-pink. Female lacks red in black malar, never has any red on hindneck. Juvenile duller than adult, with indistinct, narrow buff tips on rear crown, markings below more bar-like and often extending to flanks and belly, eyes reddish-brown, male usually with some red on nape. Race *puna* is similar to nominate but darker above, often also below, with larger breast markings, tail usually less barred, legs dull greenish, both sexes with dark red patch on hindneck, female's malar often indistinct; *cinereicapillus* is largest, distinctive, face and underparts deep cinnamon, breast with thin bars, throat partly grey, tailbars irregular, no red on nape, legs more orange-yellow. Voice. Loud whistled "tew-tew-tew", very like call of Greater Yellowlegs (*Tringa melanoleuca*); single or grouped "peck" or "kek" presumed location call and alarm (apparently shorter and higher-pitched in *cinereicapillus*), often with interspersed "clotit" or "quoi-ik-ik" in encounters (*puna*); also clear descending trill, "brrrridip", c. 2.5 seconds long with up to c. 70 elements (tends to be shorter, higher, slower in *puna*), often from rock, presumably long-distance communication; low "peea" when meeting conspecific; louder "kwa-kwa-kwa, wee-a, wee-a" or "kway-áp" calls in display.

**Habitat.** Open country and forest edge at high elevations; broken, rolling country favoured over flat land. Inhabits stony steppes and gorges, montane scrub, *Polylepis* woodland; common in grassland of Andean *puna*, less common in humid grass-shrub of páramo. Between 2000 m and 5000 m throughout *puna* zone; reports at or below 2900 m, exceptionally down to 800 m, possibly foraging parties of non-breeders.

**Food and Feeding.** Insects, including large lepidopteran and coleopteran larvae. Beetles (Scarabaeidae, Melolonthinae, Rutelinae) and noctuid moths recorded as components of diet. Gregarious: 8-10 individuals may be seen foraging together, moving considerable distances as a group; group of at least 21 birds seen feeding actively in *puna* of NE Peru. Foraging decidedly terrestrial; occasional pecks on arboreal perch indicate excitement and alertness, rather than true feeding. Preferred foraging grounds are grassy areas around rocky outcrops and other vantage points, such as cliff, rock, building, road cutting or riverbank; trees, where present, used as lookouts; feeding areas can be far from nesting grounds or roosts, and may be at lower altitudes. Starts a ground-foraging bout from vantage point, and returns to it immediately after feeding, or at slightest sign of danger. Food is sought at bases of tussocks; brushes away earth, pebbles and debris; probes into soil with remarkably long bill, digs up ground to obtain larvae hidden at depth of 5 cm or more. Feeding area is scoured evenly, searching not restricted to certain areas such as anthills. Walks on ground; in steep, rocky or densely grass-covered terrain, also hops.

**Breeding.** Season probably Sept-Nov in C Peru, and Jan-Mar elsewhere; possibly breeds also at other times of year; cold and snowfall in wet season of great influence in determining timing of nesting. Chiefly colonial, in groups of up to 10 or many more pairs, inter-nest distance sometimes only 50 cm. Displays include raising head to vertical position and then lowering it, wing-flicking, head-swinging with bobbing, tail-spreading. Nest-burrow dug in earth bank, cliff or rocky terrain, a horizontal or slightly upward-sloping entrance tunnel c. 1-1.5 m long, ending in nest-chamber 30 cm wide; nest-hole often excavated in native building, especially abandoned one (30-60 holes made in single hut over time, mostly for roosting), rarely in tree (*Polylepis*). Clutch size not documented, but 2-4 nestlings recorded; both parents feed chicks, also remove faeces; no information on incubation and fledging periods.

**Movements.** Probably some seasonal movements, with cold temperatures or snow forcing birds to retreat from high altitude to somewhat lower elevations.

**Status and Conservation.** Not globally threatened. Common to fairly common; locally very common. Noisy and conspicuous, difficult to overlook where present. Only recently recorded in Ecuador, where is uncommon and local. Occurs in Machu Picchu Historical Sanctuary (Peru), Sajama National Park (Bolivia), Lauca National Park (Chile) and Los Cardones National Park (Argentina). No known threats.

**Bibliography.** Araya & Chester (1993), Canevari *et al.* (1991), Cicero & Johnson (1995), Clements & Shany (2001), Doerl (1956, 1963), Fjeldså & Krabbe (1990), Flores & Capriles (1998), Johnson (1967), Kent *et al.* (1999), Koepcke (1970), Narosky & Yzurieta (1993), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), de la Peña (1994), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Greenfield (2001), Rocha & Peñaranda (1995), Short (1985b), Stotz *et al.* (1996), Walker (2001), Zimmer (1930).

# 153. Campo Flicker

## *Colaptes campestris*

French: Pic champêtre

German: Feldspecht

Spanish: Carpintero Campestre

**Other common names:** Campos Flicker; Field Flicker (*campestris*)

**Taxonomy.** *Picus campestris* Vieillot, 1818, Paraguay.

Race *campestris* often considered a separate species, but hybridizes with nominate in Paraguay, and probably occasionally elsewhere, and the two appear to intergrade. Birds from NE Brazil, described as race *chrysosternus*, considered indistinguishable from nominate. Two subspecies recognized.

### Subspecies and Distribution.

*C. c. campestris* (Vieillot, 1818) - S Surinam and NC Brazil (near Santarem); E Brazil (Maranhão S to Santa Catarina), N & E Bolivia (Beni, Santa Cruz) and C Paraguay.  
*C. c. campestris* (Malherbe, 1849) - C & S Paraguay, SE Brazil (Rio Grande do Sul) and Uruguay to NE & E Argentina (S to E Rio Negro).

**Descriptive notes.** c. 28-31 cm; 145-192 g, female up to c. 15 g lighter than male (*campestris*); c. 155 g (*campestris*). Male has black forehead to nape, buffish-white lores and area around eye, more golden-buff on ear-coverts, neck and upper breast; black malar region with red and buff feather tips, black chin and throat, chin often flecked white; upperparts, including wing-coverts and tertials, dark brown with narrow light brown and whitish bars, pale bars broader on scapulars and coverts, white rump variably (occasionally heavily) spotted or barred dark, uppertail-coverts barred brown and white; dark brown flight-feathers thinly barred buffish;

white; uppertail brown-black, narrow buff bars on outer webs, also on inner webs of central feathers; underparts below breast white, tinged pale yellow, with narrow dark barring, underparts frequently soiled through ground-feeding habits; underwing yellowish, darker tip and trailing edge, some spots on primary coverts; undertail as above, pale bars more obscure; longish bill pointed, culmen curved, narrow across nostrils but broad-based, black; iris chestnut to red-brown; legs green-grey or pink-tinged. Female has malar area whitish and black, without red tips. Juvenile duller than adult, dark bars broader, golden-buff areas paler and less extensive. Race *campestris* differs from nominate mainly in white to buff-white chin and throat, thus malar more conspicuous, also often more narrowly barred below, belly almost plain. Voice. Loud double or triple whistle, notes run together more than in corresponding vocalization of *C. rupicola*, heard infrequently; "week" or "keep" series as location call; wavering "wewwwwew", "gwik", "ewuh", and "pya" or "kyow"; also wavering "we-a, kwih" or "kyaw-wi" notes, like low versions of "wicka" calls of *C. auratus*; fast series of "wick" (slightly higher-pitched in *campestris*) in close contacts; also long or short series of fairly clear "oo" and "ee" notes. **Habitat.** Savanna and other grassland, campos, farmland, edges. Sub-arid scrub (*caatinga*), forest clearings and woodland edge, and tree plantations in open areas, in N of range. S race *campestris* typically inhabits open pampas, at forest edge and in clearings, and is a characteristic bird of open level country. Secondary habitats include overgrazed land, and undeveloped areas along major highways. Locations with termite (Isoptera) nests, fence posts, trees and similar structures suitable for nesting are favoured. Lowlands, to 600 m in Argentina.

**Food and Feeding.** Predominantly ants and termites, and their brood; more than 2000 ants found in 1 stomach. Adult beetles, Orthoptera, and nestlings also taken. Often in small groups; loose parties of up to 8 individuals seen foraging together, or concentrated at an anthill, sometimes joined by *C. melanochlorus*. Forages almost exclusively on the ground, among stones, at decaying fallen logs, and on roads; also visits termite mounds or anthills and other prominent structures, such as isolated trees, utility or fence poles, cacti and rocks. Regularly perches on wires. Walks when searching for food, hops to cover long distances; also hops to ascend termite hills and similar structures. Opens the large mounds of terrestrial termites; sometimes breaks into nests of Rufous Hornero (*Furnarius rufus*) to reach the nestlings. Known to hammer large holes, up to 7 cm in diameter, into buildings, but uncertain whether this behaviour designed to create roost-sites or for securing food.

**Breeding.** Jan-Apr in Surinam and Aug-Nov in Argentina. Availability of nest-sites probably a crucial factor in social behaviour; groups of 3 or 4 birds seen more commonly than pairs or solitary individuals during breeding season, but relationships within such groups not well known; sometimes in loose colonies, e.g. 5-6 nests/100 m along lines of trees. Displays with fluttering or spreading of wings to reveal bright yellow shafts; head-swinging not very conspicuous. Nest excavated at up to 12 m in tree trunk or dead stump, or in telephone pole or large fence post where available, or occasionally in nest of arboreal termites (*Constrictotermes cypergaster*); in mound of terrestrial termites (*Cornitermes cumulans*) and in banks in treeless country. Clutch 4-5 eggs; incubation by both partners; incubation and fledging periods not documented; family-members stay together for an extended period.

**Movements.** Resident; possibly wanders to some extent.

**Status and Conservation.** Not globally threatened. Generally common; locally very common. Occurs in several protected areas, e.g. Beni Biosphere Reserve (Bolivia), Monte Pascoal, Aparados da Serra and Serra do Cipó National Parks, Rio Doce State Park and Sooretama Biological Reserve (Brazil), and Iguaçu National Park and Costanera Sur Ecological Reserve (Argentina). Benefits from deforestation; clearance of forest for road-building creates new areas of habitat for this open-country species, enabling it to expand its range; can now be observed in clearings in subtropical moist forest, and on so-called wasteland bordering major highways.

**Bibliography.** Aleixo & Galetti (1997), dos Anjos & Schuchmann (1997), Belton (1984), Bencke & Kindel (1999), Brace *et al.* (1997), Buzzetti (2000), Canevari *et al.* (1991), Capper *et al.* (2000), Castro (1991), Contreras *et al.* (1990), Dubs (1992), Ferreira de Vasconcelos & Melo-Júnior (2001), Figueiredo & Lo (2000), Figueiredo *et al.* (2000), Fjeldså & Krabbe (1990), Friedmann (1927), Haverschmidt & Mees (1994), Hayes (1995), Klimaitis & Moschione (1987), López (1997), Madroño, Robbins & Zyskowski (1997), Marini (2001), Marini *et al.* (1997), Melo-Júnior (2001a), Parker & Goerck (1997), de la Peña (1994, 1996), Pinto & Camargo (1961), Raw (1997), Remsen & Traylor (1989), do Rosário (1996), Scott & Brooke (1985), Short (1969b, 1975, 1985b), Sick (1993), da Silva *et al.* (1997), Stager (1961a), Stotz *et al.* (1996), Stradi & Hudon (1998), Stradi *et al.* (1998), Tobias *et al.* (1993), Tubelis & Tomás (1999), Venturini *et al.* (2001).

Genus *CELEUS* Boie, 1831

## 154. Rufous Woodpecker

*Celeus brachyurus*

**French:** Pic brun      **German:** Rötelspecht      **Spanish:** Carpintero Rufo  
**Other common names:** Brown Woodpecker

**Taxonomy.** *Picus brachyurus* Vieillot, 1818, Java.

Sometimes placed in a monospecific genus *Micropternus*. Taxonomic position uncertain; not very closely related to other, Neotropical species of present genus, and possibly closer to genus *Picus*; further study required. Considerable individual variation rendering racial delimitation difficult; proposed races *hadius* (Sumatra) and *celanephis* (Nias I) inseparable from continental *squamigularis*. Nine subspecies recognized.

**Subspecies and Distribution.**

- C. b. humei* (Kloss, 1918) - N India (Himachal Pradesh) E to W Nepal.  
*C. b. jerdonii* (Malherbe, 1849) - W India (S from S Gujarat) S to Sri Lanka.  
*C. b. phaeiceps* (Blyth, 1845) - C Nepal and E India E to SE Tibet, Myanmar and S China (W & S Yunnan) and S to S Thailand.  
*C. b. fokiensis* (Swinhoe, 1863) - S & SE China and N Vietnam.  
*C. b. holroydi* (Swinhoe, 1870) - Hainan.  
*C. b. annamensis* (Delacour & Jabouille, 1924) - Laos, Cambodia and S Vietnam.  
*C. b. squamigularis* (Sundevall, 1866) - S peninsular Thailand S to Sumatra, including offshore islands of Bangka, Belitung and Nias.  
*C. b. brachyurus* (Vieillot, 1818) - Java.  
*C. b. badiosus* (Bonaparte, 1850) - Borneo and N Natuna Is.

**Descriptive notes.** c. 25 cm; 55-84 g (*squamigularis*, *badiosus*), 82-107 g (*jerdonii*), 92-114 g (*phaeiceps*). Male has dark brown forehead to nape and short crest, broad red feather tips beneath eye back to front of ear-coverts, dark throat with buff feather tips; rest of head and body plumage dark rufous to chestnut, upperparts very narrowly barred black, flanks to undertail-coverts with widely spaced thin black bars, belly sometimes with thin broken bars; wings similar to upperparts; tail also narrowly dark-barred, broader black tips; underwing rufous, barred black; short bill, culmen slightly curved, rather narrow-based.

dark grey, blacker tip; iris reddish to brown, narrow orbital skin grey; legs blue-grey or bluish-green to brown. Female lacks red on side of head. Juvenile as adult, variably barred, often less heavily, or sometimes with bars extending to breast. Races highly variable, including individually, in ground colour of plumage, some much paler than others: *humei* is large, pale, with greyish head, streaked throat; *jerdonii* is smaller and more rufous than previous, with paler head, scaly throat markings; *phaeiceps* is large, rather dark rufous, with brownish head; *squamigularis* is fairly small, generally much paler than previous, with heavily streaked throat, belly strongly barred with arrowheads (barring less extensive in Sumatran population); *badiosus* has long bill, contrasting black tail narrowly barred rufous, unbarred black, little or no barring on belly, throat feathers black-based with chestnut tips and buff edges; *fokiensis* is distinctive, with creamy head streaked black on crown, heavily black-streaked throat, broad black bars above, sooty-brown and little streaked below, greyer or browner breast, proportionately longest tail; *annamensis* resembles previous, but slightly smaller, head darker; *holroydi* is smaller than previous, very dark chestnut all over, with narrow bars above, throat streaked brown, flanks barred black. Voice. Highly vocal: series of 3 nasal "kweep" or "keenk" notes delivered in less than 1 second (sometimes pause before final note), reminiscent of calls of Common Myna (*Acridotheres tristis*); in encounters 4 or 5 "kweek" notes, some perhaps similar to variable "whi-chi" in same context; slightly falling accelerating series 2 seconds long of up to 16 notes, may be repeated several times, probably as territorial announcement and contact between pair-members. Drumming highly distinctive, single roll 1.5-5 seconds long, slows gradually to halt like stalling motorcycle engine, "ddddd-d-d-d---dt", rolls 2-3 minutes apart, delivered commonly, often on bamboo, by both sexes.

**Habitat.** Primary forest and secondary forest, both evergreen and deciduous. Open forest, secondary growth, forest edge and scrub preferred; habitats include sal (*Shorea*) forest, and has strong liking for bamboo jungle, at least locally. May also visit reedbeds and mangroves. Mostly well away from human habitations in some areas; may be found in plantations, palm groves and gardens in others, e.g. in Sumatra. Resident from plains up to 610 m in Sri Lanka, to 1530 m in Nepal; to 1450 m in China and SE Asia, but mostly below 1000 m in Thailand and Malay Peninsula; to 1740 m in Borneo.

**Food and Feeding.** Chiefly ants and their brood, particularly of genus *Crematogaster*, but also *Pheidole* and *Oecophylla*; also termites (Isoptera), other insects. Vegetable matter taken occasionally, includes fruits (e.g. *Ficus*), nectar, sap. Often in pairs; sometimes with mixed-species flocks. Forages at all levels, including high canopy of tall forest, and occasionally on ground; densely vegetated sites generally preferred, but more open ones also visited at times. May perch crosswise on twigs. Searches vines, trunks, branches, twigs, bamboo; on ground, observed to seek food in small termite mounds or anthills, even in cow-pats; also explores rotting logs. Chief feeding techniques are gleaning and probing, with occasional weak and barely audible blow. Pecks at *Crematogaster* nests from a perch close by; clings at nest, tears it apart, gleans ants that swarm out, also picking them from its plumage and feet. Also observed to puncture banana stems to feed on the oozing sap. Very active, almost constantly on the move, remains at a site only if abundant food source, e.g. ants, present.

**Breeding.** Apr-Jun in Nepal, Sikkim and N Myanmar, Feb-Jun in S India and Sri Lanka, Jan-Apr in Thailand and Malaysia, May-Jun in Sumatra, and in Apr and Sept in Java. Displays include tail-spreading, head-swinging and body-swinging. Nest-hole, dug by both sexes, is in active arboreal nest of ants, mostly of genus *Crematogaster* but sometimes others (e.g. *Plagiolepis*), usually high

up on tree trunk, occasionally lower (c. 3 m) around fork in sapling; less often, hole excavated in tree or stub. Clutch 2-3 eggs, up to 7 recorded rarely (China), clutch size increasing S to N; both sexes incubate, period 12-14 days; both also feed chicks, by regurgitation, fledging period not documented.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Locally common in India, uncommon in Nepal, scarce in Sri Lanka; common in China; fairly common to common throughout SE Asia and Greater Sunda. Occurs in many protected areas throughout its extensive range, e.g. Corbett, Periyar and Kaziranga National Parks (India) and Cuc Phuong National Park (Vietnam). Although habitat loss could possibly limit or reduce its populations, this woodpecker readily accepts more open forest and a variety of secondary habitats, so long as plenty of nests of arboreal ants are available.

**Bibliography.** Ali (1996), Ali & Ripley (1983), Ali *et al.* (1996), Andrew (1992), Baker (1919), van Balen (1999), Bangs & Van Tyne (1931), Betts (1934), Biswas (1961b), Bucknill & Chasen (1990), Deignan (1945), Duckworth & Kelsh (1988), Eames & Robson (1992), Edgar (1933), Étchécopar & Hùe (1978), Grimmett *et al.* (1998), Hails & Jarvis (1987), Harrison (1999), Harvey (1990), Henry (1998), Hoffmann (1998), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Jeyarajasingam & Pearson (1999), Lainer (1999), Lamsfuss (1998), Lekagul & Round (1991), Ludlow (1937, 1944), MacKinnon (1988), MacKinnon & Philipps (1993, 2000), van Marle & Voous (1988), McClure (1998), Medway & Wells (1976), Mees (1986), Meyer de Schauensee & Ripley (1940), Phillips (1978), Proud (1958), Riley (1938), Ripley (1982), Robinson & Kloss (1921-1924), Robson (2000), Santharam (1997, 1998c), Sargeant (1997), Short (1973d, 1985b), Smythies (1986, 1999), Stepanyan (1995), Taylor (1961), Vowles & Vowles (1997), Wells (1985, 1999), Wilkinson, Dutton & Sheldon (1991), Wilson (1898), Zacharias & Gaston (1999), Zhao Zhengjie (1995).

## 155. Cinnamon Woodpecker

*Celeus loricatus*

**French:** Pic cannelle      **German:** Rotkehlspiecht      **Spanish:** Carpintero Canelo

**Taxonomy.** *Meiglyptes loricatus* Reichenbach, 1854, Peru.

Possibly not very closely related to others of genus. Wide individual variation, making racial delimitation difficult; birds from C Magdalena Valley, in Colombia, described as race *degener*, but differences from *innatus* considered insignificant. Designated type locality of Peru falls outwith known range of species, and may require revision. Four subspecies recognized.

**Subspecies and Distribution.**

- C. l. diversus* Ridgway, 1914 - E Nicaragua S to W Panama.  
*C. l. mentalis* Cassin, 1860 - Panama and NW Colombia.  
*C. l. innatus* Todd, 1917 - N Colombia.  
*C. l. loricatus* (Reichenbach, 1854) - W Colombia to SW Ecuador (S to Guayas).

**Descriptive notes.** c. 19-23 cm; 74-83 g. Male has rufous head and bushy crest, crown streaked black, red-tipped black chin, throat and malar area, sometimes also a few red tips around eye; upperparts, including wing-coverts and tertials, dark rufous, rump paler, all narrowly barred black; blackish flight-feathers with very broad rufous bars; uppertail black, very broadly barred buff to whitish; upper breast light rufous with black edges and tips, rest of underparts paler buff, with striking bold black markings on breast, arrowhead bars on flanks and belly to undertail-coverts; rufous underwing barred black on flight-feathers;

medium-long bill almost pointed, culmen slightly curved, narrow across nostrils, greyish to yellowish; iris red; legs grey. Female lacks red on throat, head rather uniformly rufous. Juvenile much as adult but dusky-mottled on throat, less regularly marked below, male with red on face. Races differ mainly in amount of barring: *diversus* is largest, more cinnamon-tinged than nominate, has large red tips on throat, narrower black bars above, more widely spaced narrower bars below, yellowish bill; *mentalis* is smaller than previous, paler below, with less barring above and below; *innatus* resembles previous, but even less marked, very weakly barred or even unbarred above, may lack crown streaks, plain below but for a few breast spots. Voice. Accelerating series of 3-5 fast ringing notes, descending in pitch and amplitude, e.g. "pee-pee-pee-pu", sometimes introduced with "chuwééoo": sharp, descending rolling chatter when agitated; also hard "chikikikirk", squeaky "titititi-toó", and "chweé-titit". Drumrolls rather slow, short.

**Habitat.** Inhabits humid and wet forest, rarely in drier areas; occasionally visits forest edge, nearby semi-open areas, old second growth, and clearings. Occurs in lowlands and foothills, from sea-level up to 760 m in Costa Rica and Panama, up to 1500 m in Colombia; to 800 m in Ecuador.

**Food and Feeding.** Ants and termites; also fruit, e.g. ripening bananas. Usually forages singly or in pairs; only occasionally joins mixed-species flocks. Active in or near canopy in forest interior; also at lower levels, particularly in open areas. Generally visits trunks, often thin ones, and twigs and branches; often clings to seedlings and bushes in undergrowth. Pecks frequently, and gleans to some extent, observed to peck into swollen nodes of laurel (*Cordia alliodora*) twigs and *Cecropia* trunks to reach ants, and into tunnels for termites.

**Breeding.** Mar-May in Costa Rica and Jan-Apr in Colombia. Hole excavated by both sexes, at 6-9 m in soft wood of living or recently dead tree. Clutch size and incubation and fledging periods apparently not described.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally uncommon, but locally fairly common. Normally inconspicuous, more often heard than seen. Occurs in a number of protected areas throughout range, e.g. Braulio Carrillo National Park and Finca La Selva (Costa Rica), Los Katíos National Park, Río Nambí Nature Reserve and El Pangán Reserve (Colombia), and Manglares-Churute Ecological Reserve (Ecuador). Recorded at several sites in W Panama (e.g. El Copé and Santa Fe).

**Bibliography.** Anon. (1998b), Blake & Loiselle (2000, 2001), Butler (1979), Cooper (1997), Gillespie (2001), Haffer (1974, 1975), Hilty (1997), Hilty & Brown (1986), Meyer de Schauensee (1982), Olog (1968), Pople *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely *et al.* (1998), Robbins *et al.* (1985), Salaman (1994), Slud (1960, 1964), Sules (1985), Sules & Skutch (1989), Sules *et al.* (1999), Stotz *et al.* (1996), Wetmore (1968a).

## 156. Scaly-breasted Woodpecker

*Celex grammicus*

**French:** Pic de Verreaux    **German:** Gelbflankenspecht    **Spanish:** Carpintero Rojizo  
**Other common names:** Scale-breasted Woodpecker

**Taxonomy.** *Picus grammicus* Natterer & Malherbe, 1845, Marabitanas, upper Rio Negro, Brazil. Forms a superspecies with *C. undatus*. Proposed race *undulatus*, described from R Mocho (R Caura area, SC Venezuela), is known only from type locality; now included within nominate. Four subspecies recognized.

**Subspecies and Distribution.**

*C. g. grammicus* (Natterer & Malherbe, 1845) - SE Colombia and S Venezuela S to NE Peru and W Brazil; also French Guiana (Nouragues area).

*C. g. verreauxii* (Malherbe, 1858) - E Ecuador and adjacent NE Peru.

*C. g. subcervinus* Todd, 1937 - Brazil, S of R Amazon, E to lower R Tapajós and S to N Mato Grosso.

*C. g. latifasciatus* Seilern, 1936 - SE Peru and SW Brazil (upper R Madeira) S to N Bolivia (Beni).

**Descriptive notes.** c. 23-26 cm; 63-75 g (*grammicus*), 77-82 g (*verreauxii*), 75-87 g (*latifasciatus*). Male has rufous-chestnut forehead to pointed crest usually streaked black (streaking variable), broad red patch on cheeks and malar region extending to front part of ear-coverts, rest of plumage mostly rufous-chestnut; neck side barred black, upperparts narrowly barred black; rump pale greenish-yellow to yellow-buff, very occasionally with some red-tipped feathers; rufous-chestnut uppertail-coverts occasionally slightly barred; blackish flight-feathers narrowly edged rufous, bases paler greenish-yellow; uppertail brown-

black, feathers edged chestnut, base sometimes wholly chestnut; flanks paler rufous-chestnut to yellowish-buff; breast with black bars or arrowhead marks, narrower on lower breast, sparse spots on belly; underwing dull brown, paler yellowish coverts and flight-feather bases; undertail brown or yellow-brown, cinnamon base; shortish bill slightly chisel-tipped, culmen curved, narrow across nostrils, greenish to yellow-green or ivory; iris red; legs dark greenish-grey to grey. Differs from *C. undatus* in much darker head, unbarred tail, darker underparts. Female has red of face replaced by rufous-chestnut. Juvenile as adult, but head darker with some blackish areas, usually paler upperparts more broadly barred, male with some red in malar. Race *verreauxii* resembles nominate, but less barred below; *subcervinus* has rump and flanks more cinnamon to buff, lacking yellow tone; *latifasciatus* is distinctive, pale cinnamon-coloured above with yellow or buffish feather bases visible, very pale rump, mantle broadly barred, much paler ground colour below. **VOICE.** Common call a loud, abrupt, slightly nasal whistle, "curry-kuuu" or "doit-gua" or "kuwee? kuuu", clearly enunciated; very loud and metallic "pring-pring!" notes, in series of up to 4, also heard.

**Habitat.** Inhabits rainforest, humid *terra firme* and *várzea* forests, forest edge, second growth, and savanna with scattered trees. Ranges from 100 m up to 900 m, locally up to 1140 m; to c. 500 m in Ecuador.

**Food and Feeding.** Ants and fruit. Sometimes in groups of 3 or 4 birds, probably family parties; frequently associates with mixed-species groups. Forages inconspicuously in middle to upper levels, on trunks and larger limbs, also on vines. Pecks rapidly; probes and gleans at bark surface.

**Breeding.** Feb-Apr in Venezuela, possibly somewhat later in Brazil. No other information available.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Rather uncommon to common; uncommon in Peru; uncommon to fairly common in Ecuador. Inconspicuous and not often seen. Occurs at La Selva (Ecuador), Tambopata and Alpahuayo-Mishana Reserves (Peru) and Rio Cristalino Private Reserve (Brazil). Study required on its ecology and breeding biology.

**Bibliography.** Allen (1995), Borges *et al.* (2001), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Donahue (1994), Friedmann (1948), Haffer (1974), Hilty & Brown (1986), Meyer de Schauensee (1982), Meyer de Schauensee

& Phelps (1978), Olrog (1968), Oren & Parker (1997), Parker *et al.* (1982), Peres & Whittaker (1991), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Robinson & Terborgh (1997), Sick (1993), da Silva (1996), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Tostain *et al.* (1992).

## 157. Waved Woodpecker

*Celex undatus*

**French:** Pic ondé    **German:** Olivbüzelspecht    **Spanish:** Carpintero Ondoso

**Taxonomy.** *Picus undatus* Linnaeus, 1766, Surinam.

Forms a superspecies with *C. grammicus*. Three subspecies recognized.

**Subspecies and Distribution.**

*C. u. undatus* (Linnaeus, 1766) - E Venezuela (E Sucre S to E Bolívar), the Guianas, and NE Brazil N of Amazon (W from middle and lower R Negro).

*C. u. amacurensis* Phelps, Sr. & Phelps, Jr., 1950 - Delta Amacuro (NE Venezuela).

*C. u. multifasciatus* (Natterer & Malherbe, 1845) - NE Brazil S of Amazon, from C Pará E to lower R Tocantins and NW Maranhão border.

**Descriptive notes.** c. 23-24 cm; male 61-73 g, female 58-68 g. Male has broad red band from upper bill back to front edge of ear-coverts; rest of head light chestnut-rufous, crown and crest often paler and sometimes barred, rear ear-coverts and neck side finely spotted or streaked; chin and throat cinnamon-buff with black spots or bars; entire upperparts, including wing-coverts and tertials, rufous-chestnut, usually paler or yellower on rump, all broadly barred black; black flight-feathers with cinnamon-rufous bars; black uppertail with variable number of rufous bars, sometimes none; rufous below, paler in lower regions, breast with irregular

wavy bars, variable (breast feathers sometimes black with narrow pale edges, all black when abraded), belly and flanks with more regular bars or arrowheads; underwing cinnamon, barred bases of flight-feathers; undertail as above but duller, sometimes tinged yellowish; shortish bill almost pointed, culmen curved, fairly narrow across nostrils, dull yellow to yellow-green; iris red-brown to red; legs green-grey. Considerable variation in intensity of black barring; Brazilian populations of nominate tend to show heavier black barring, with upper breast appearing almost solid black. Female lacks red on head, and generally more heavily barred. Juvenile duller than adult, less barred above. Race *amacurensis* is darker, more chestnut, than nominate, with head same colour as upperparts (not paler), rump more cinnamon-rufous (not yellow), crown unmarked, all bars narrower; *multifasciatus* is somewhat bigger than others, proportionately shorter-tailed, paler, more buffy, with head streaked (not barred), tail often unbarred, paler below, has blackish bill with paler lower mandible. **VOICE.** Loud "wit-koa", very like corresponding call of *C. grammicus*; soft, whispered "kowahair", rising in pitch, also described. Both sexes drum.

**Habitat.** Most frequent in dense rainforest, at up to 500 m; occasionally in more open terrain of savanna regions, at forest edge, and near rivers.

**Food and Feeding.** Ants and termites; occasionally seeds. Forages inconspicuously in treetops; sometimes joins mixed-species feeding flocks.

**Breeding.** Season from end of May to Aug in the Guianas; possibly in earlier part of that period in SE of range. Nest in dead or live tree at 4-30 m. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon. Occurs in Canaima National Park and Imataca Forest Reserve and El Dorado (Venezuela). Observed at Mana, in French Guiana. Poorly known woodpecker, unobtrusive and not often seen. Research on its ecology and breeding biology desirable, and censuses required to determine its population status, but fieldwork not easy in areas inhabited by this species.

**Bibliography.** Cohn-Haft *et al.* (1997), Haffer (1974), Haverschmidt & Mees (1994), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), O'Brien (1979), Olrog (1968), Ruschi (1979), Sick (1993), Snyder (1966), Stotz *et al.* (1996), Thiollay & Jullien (1998), Tostain *et al.* (1992), Wheatley (1994).

PLATE 42

## 158. Chestnut-coloured Woodpecker

*Celeus castaneus*

**French:** Pic roux      **German:** Kastanienspecht      **Spanish:** Carpintero Castaño  
**Other common names:** Chestnut Woodpecker(!)

**Taxonomy.** *Picus castaneus* Wagler, 1829, no locality = Veracruz, Mexico. Possibly forms a superspecies with *C. elegans*, *C. lugubris* and *C. flavescens*. Monotypic.  
**Distribution.** E Mexico (from S Veracruz, N Oaxaca) S to W Panama.

**Descriptive notes.** c. 23-25 cm; 80-105 g. Male has broad red band from bill base back to lower cheeks, red feather tips around eye, and sometimes along crown side; rest of head ochraceous-buff to cinnamon-buff, crest more golden; upperparts, including wing-coverts and tertials, chestnut or rufous-chestnut, rump yellow, mantle, back and wing-coverts with variable number of widely spaced broken black bars, uppertail-coverts usually spotted or barred black; dark rufous-brown flight-feathers, blacker tips, rarely with sparse spots or bars on secondaries; uppertail blackish, base often dark rufous-chestnut; dark rufous-chestnut below.

low, golden-buff on inner flanks (feather bases), all with black chevrons or more regular bars, markings narrower on belly; underwing-coverts yellowish, cinnamon bases to dark-tipped flight-feathers; rather short bill slightly chisel-tipped, culmen curved, fairly narrow across nostrils, pale greenish to pale ivory-yellow, often blue-green base; iris chestnut to brown, orbital ring grey or blackish; legs dark olive to grey. Female lacks red on head. Juvenile duller than adult, often dark bars on face, less barred on belly. Voice. Sibilant descending whistle, "peew" or "kheeu", often followed by 2-10 sharp nasal "wet" notes; regular series of "howp" notes, often with terminal "r'rrp"; also single low "kwar"; series of sharp "wik-kew" in excitement. Drumroll c. 1.5 seconds, shorter and softer than that of e.g. *Melanerpes pucherani*.

**Habitat.** Prefers dense humid evergreen and semi-deciduous forest, tall second growth; also forest edge, and densely foliated trees with epiphytes in semi-open areas, occasionally mangroves. Lowlands, also entering foothills, to 500 m, locally to 750 m, rarely 1000 m.

**Food and Feeding.** Mainly ants and termites (Isoptera), and other insects; some fruit, and arillate seeds (e.g. *Stemmadenia*), possibly also cultivated crops (cacao). Usually singly or in pairs; occasionally with mixed-species flocks. Forages mainly in canopy and subcanopy, down to middle levels along edges. Explores trees with dense foliage and epiphytes in semi-open, more often on trunks and larger limbs than *C. loricatus*. Sometimes clings to foliage, and moves sideways along a twig; able to obtain fruits hanging from distal ends of branches. Pecks into tunnels and hard nests of arboreal termites, and in *Cecropia* trunks; also pries off bark flakes, eating prey thus uncovered. Pecking and probing are most frequent foraging techniques, followed by hammering; gleans rarely.

**Breeding.** Mar-Jun, sometimes Aug, in N of range; Feb-Jul in Costa Rica and Panama. Nest excavated by both sexes, 4-21 m up in soft wood of living or recently dead tree, sometimes much lower (e.g. 0-9 m) in palm. Clutch 3 or 4 eggs (Belize). No other information.

**Movements.** Some seasonal movements; wanders into coastal scrub and mangrove in winter.

**Status and Conservation.** Not globally threatened. Fairly common to common in Mexico, less common farther S. Occurs in several protected areas, including Finca La Selva (Costa Rica). Alleged to cause some damage in commercial cacao plantations.

**Bibliography.** Angehr (2001), Anon. (1998b), Binford (1989), Blake & Loiselle (2000, 2001), Cooper (1999), Dearborn (1907), England (2000), Friedmann *et al.* (1957), Gillespie (2001), González-García (1993), Howell & Webb (1995), Kilham (1979a), Land (1970), Paynter (1955), Ridgely & Gwynne (1989), Short (1972a, 1975, 1985b), Stud (1960, 1964), Smithe (1966), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Vallety & Whitmore (1997), Wetmore (1968a).

## 159. Chestnut Woodpecker

*Celeus elegans*

**French:** Pic mordoré      **German:** Fahlkopfspecht      **Spanish:** Carpintero Elegante  
**Other common names:** Elegant Woodpecker, Pale-crowned Crested Woodpecker; Russet-crested/Rufous-crested Woodpecker (*elegans* group); Chestnut-crested Woodpecker (*jumanus* group); Yellow-crested Woodpecker (*leotaudi*)

**Taxonomy.** *Picus elegans* P. L. S. Müller, 1776, Cayenne. Possibly forms a superspecies with *C. castaneus*, *C. lugubris* and *C. flavescens*. Dark-crowned, short-crested races *jumanus* and *citreopygius* sometimes considered to form a separate species. Birds from upper R Branco, in N Brazil, described as race *approximans*, but appear inseparable from nominate; proposed race *saturatus* (N Bolivia) indistinguishable from *jumanus*. Form "*C. immaculatus*", known only from type specimen, supposedly from Panama, appears to be an aberrant form of nominate race of present species with erroneous locality data. Six subspecies recognized.

**Subspecies and Distribution.**

*C. e. hellmayri* Berlepsch, 1908 - E Venezuela, Guyana and most of Surinam.  
*C. e. leotaudi* Hellmayr, 1906 - Trinidad.  
*C. e. deltanus* Phelps, Sr. & Phelps, Jr., 1950 - Delta Amacuro (NE Venezuela).  
*C. e. elegans* (P. L. S. Müller, 1776) - E Surinam, French Guiana, and N Brazil N of Amazon (Roraima to Amapá).  
*C. e. jumanus* (Spix, 1824) - E Colombia and S Venezuela (Amazonas, S Bolívar) through W & C Brazil (N of Amazon E to R Negro and S of Amazon E to Maranhão, and S to Rondônia and Mato Grosso) to N Bolivia.  
*C. e. citreopygius* P. L. Sclater & Salvin, 1868 - E Ecuador and E Peru.

**Descriptive notes.** c. 26-32 cm; 138-168 g (*hellmayri*), 112-146 g (*jumanus*), 93-139 g (*leotaudi*). Male has buffish-cream forehead, crown and long crest, broad red malar area and cheek; rest of head and neck, chin and throat deep chestnut-brown; deep rufous-chestnut upperparts occasionally

with faint black bars, rarely with yellow feather bases showing through, cream-buff rump occasionally with some red-tipped feathers, uppertail-coverts as rump or sometimes with rufous tips; wing-coverts with small white spots or thin shaft streaks, creamy area on alula; secondaries barred brown on inner webs, and sometimes on outer, blackish-brown outer primaries usually with rufous bars at base of inner webs; uppertail blackish, rufous on outermost (concealed) feather; dark chestnut-brown below, belly and vent sometimes paler, flanks paler creamy cinnamon-buff and often obscurely barred; underwing mainly cream-buff or pale cinnamon, browner flight-feathers, usually some barring; short bill slightly chisel-tipped, culmen curved, fairly narrow across nostrils, ivory to yellow or greenish-yellow, darker tip; iris red-brown to red, orbital ring blue; legs olive to dark grey. Female lacks red moustache. Juvenile much as adult, but dull blackish on face, usually mottled darker below, male soon acquires red feathers in malar, also sometimes on forehead and around eyes. Race *hellmayri* differs from nominate in somewhat darker plumage, darker crown, more spots on wing-coverts, spots on scapulars, more barred primaries; *deltanus* is even darker on crown; *leotaudi* is much smaller than nominate, paler and brighter, with tawny crown, yellower rump; *jumanus* is darker overall than preceding races, also has shorter crest, rufous tips on back and wing-coverts, no white spots, more rufous tertials and secondaries, buffish thighs; *citreopygius* is also short-crested but blacker, less rufous, than previous, with contrasting red cheekband. Voice. Descending "wewa ew-ew-ew-ew-ew" or sarcastic-sounding "har-hahaha" as territorial call, and rattling screeches, e.g. "whick-frrr" or grating "wháa-jeer", occasionally rapidly repeated several times; also "wick-wick-wick-wick-wick", mellow "gwarrr", nasal "kyeenh". Both sexes drum, frequently and loudly in breeding season, double rap as "dop-dop".

**Habitat.** Variety of tall dense and light forests, including humid *terra firme*, gallery and *várzea* forests, and forest edge; also occupies secondary habitats, such as cocoa plantations. Lowlands, from sea-level to 1000 m in Venezuela, to 500 m in Colombia and to 1100 m in Peru; mostly below 500 m but recorded at 700 m in Ecuador.

**Food and Feeding.** Ants and termites (Isoptera); also dipteran larvae. Fruits (e.g. *Cecropia*, citrus and introduced mango) and berries also taken, sometimes in large quantities. Alone or in pairs, or in loose groups of up to 5 birds, frequently with mixed-species flocks. Forages inconspicuously, mainly at low to medium heights, from understorey up to subcanopy; moves along larger limbs and trunks. Techniques include gleaning from bark, hammering into arboreal termitaria. Hangs upside-down to reach for fruit.

**Breeding.** Apr-May in Trinidad and French Guiana; specimens with enlarged gonads in Jan-Feb in S Venezuela and NW Brazil. Nest-cavity in dead tree or stub; clutch 3 eggs. No other information available.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Relatively common; very common in NE Venezuela; uncommon to locally fairly common in Ecuador and Peru. Occurs in several protected areas, e.g. Imataca Forest Reserve and El Dorado (Venezuela), Asa Wright Nature Centre (Trinidad), and Cuyabeno Reserve (Ecuador). Observed at Emerald Towers (Guyana), around Iquitos (Peru), and in area of Manaus (Brazil). Generally less unobtrusive than most congeners, and therefore better known.

**Bibliography.** Bond *et al.* (1989), Brace *et al.* (1997), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Donahue (1994), Friedmann (1948), Gilliard (1941), González (1998), Haverschmidt & Mees (1994), Herklots (1961), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Oren & Parker (1997), Peres & Whittaker (1991), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Robinson (1997), Robinson & Terborgh (1997), Short (1972a, 1975), Sick (1993), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Thiollay & Julien (1998), Tostain *et al.* (1992), Willis & Oniki (1990).

## 160. Pale-crested Woodpecker

*Celeus lugubris*

**French:** Pic à tête pâle      **German:** Blassschopfspecht      **Spanish:** Carpintero Lúgubre

**Taxonomy.** *Celeopicus lugubris* Malherbe, 1851, Mato Grosso, Brazil. Possibly forms a superspecies with *C. castaneus*, *C. elegans* and *C. flavescens*. Sometimes treated as conspecific with last of these. Has apparently hybridized, rarely, with *C. elegans*. Proposed race *roosevelti* (W Mato Grosso) regarded as synonymous with nominate. Two subspecies currently recognized.

**Subspecies and Distribution.**

*C. l. lugubris* (Malherbe, 1851) - E Bolivia and WC Brazil (W Mato Grosso).  
*C. l. kerri* Hargitt, 1891 - Paraguay (except extreme E) and WC Brazil (S Mato Grosso) to NE Argentina (E Formosa, Corrientes).

**Descriptive notes.** c. 23-24 cm; 115-130 g (*lugubris*), 134-157 g (*kerri*). Distinctive. Male has brown lores, broad red malar and cheekband, red occasionally continuing to forehead and around eyes; rest of head and long pointed crest, also chin and throat, pale blond to buffish, sometimes tinged cinnamon, often some brown feathering on neck side; upperparts dark rufous-black with narrow whitish to pale cinnamon-buff bars, lower back and rump blond to cream-buff or sometimes with cinnamon tinge; longest uppertail-coverts rufous with black subterminal bars; blackish wing-coverts edged whitish to pale buff; blackish-brown flight-

feathers barred rufous on basal half, tertials fully barred rufous; uppertail black, concealed outer feathers rufous with black spots; neck and underparts dark sooty-rufous, usually a few brighter rufous feather edges, more creamy and rufous on rear inner flanks; creamy thighs variably barred

dark; black undertail-coverts with rufous bars; brown underwing barred pale buff or cinnamon, axillaries and coverts creamy; fairly long bill slightly chisel-tipped, culmen curved, rather narrow across nostrils, greyish to horn-coloured, paler lower mandible; iris dark red to red-brown, orbital ring blue-grey; legs grey. Distinguished from *C. flavescens* by somewhat paler general coloration, pale rump and tail-coverts, rufous instead of white wingbars. Female lacks red on face, has cheeks barred or scaly brown. Juvenile resembles adult, but has large blackish areas on head, barring above irregular. Race *kerri* is slightly larger and darker than nominate. Voice. Call "wee-wee-week". Drums weakly.

**Habitat.** Semi-deciduous forest, *cerrado* woodland and dry Chaco woodland; frequently seen in areas with palms. Lowlands.

**Food and Feeding.** Ants and their brood, including those of the genera *Camponotus*, *Crematogaster*, *Dolichoderus* and others. Utilizes the middle stratum. Forages by probing, gleaning and pecking; excavated dead wood to gain access to tunnels of ants, which are obtained with the sticky tongue.

**Breeding.** Sept-Nov, or later in S. Nest-hole excavated in tree or dug into arboreal nest of ants or termites, at 4-10 m. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally fairly common throughout much of range. Occurs in several protected areas, e.g. Das Emas and Chapada dos Guimarães National Parks (Brazil) and Pilcomayo National Park (Argentina). Not well known; research required to ascertain more about its ecology and breeding behaviour.

**Bibliography.** Brace *et al.* (1997), Canevari *et al.* (1991), Chebez *et al.* (1999), Contreras *et al.* (1990), Davis (1993), Dubs (1992), Flores *et al.* (2001), Hayes (1995), Hayes & Scharf (1995a, 1995b), López (1997), Mazar Barnett & Pearman (2001), Meyer de Schauensee (1982), Miserendino (1998), Narosky & Yzurietta (1993), Olrog (1968), Oniki & Willis (1999), de la Peña (1994), Remsen & Traylor (1989), Ruschi (1979), Short (1972a, 1975), Sick (1993), Stotz *et al.* (1996), Wetmore (1926), Willis & Oniki (1990).

## 161. Blond-crested Woodpecker

### *Celeus flavescens*

French: Pic ocré

German: Blondschofpecht

Spanish: Carpintero Amarillento

**Taxonomy.** *Picus flavescens* J. F. Gmelin, 1788, Rio de Janeiro, Brazil.

Possibly forms a superspecies with *C. castaneus*, *C. elegans* and *C. lugubris*. Sometimes treated as conspecific with last of these. Nominate and race *ochraceus* appear to intergrade in CE Brazil (SW Bahia to Espírito Santo), where intermediate race *intercedens* seems to be absent. Three subspecies recognized.

**Subspecies and Distribution.**

*C. f. ochraceus* (Spix, 1824) - E Brazil, from W Pará (S of Amazon) to Atlantic coast and S to E Bahia and Espírito Santo.

*C. f. intercedens* Hellmayr, 1908 - W Bahia to Goiás and Minas Gerais.

*C. f. flavescens* (J. F. Gmelin, 1788) - CE & SE Brazil (S Bahia to Rio Grande do Sul) to E Paraguay and NE Argentina (Misiones).

**Descriptive notes.** c. 25-30 cm; 110-165 g (*flavescens*). Distinctive, striking woodpecker. Male has broad red malar and cheekband, red sometimes spreading beneath eye, occasionally some red on lower forehead; rest of head, including long pointed crest, together with chin, throat and upper neck, pale creamy-buff to yellowish-white, sometimes a few dark spots on lores, often black streaks or feather centres on foreneck side; black mantle to upper back and scapulars narrowly barred white, lower back to uppertail-coverts buffish-white to pale yellow, tail-coverts sometimes with black barring; black wing-coverts edged and

barred white; black flight-feathers narrowly barred white, tertiaries with white tips and diagonal bars; uppertail black, concealed outer feathers edged or barred whitish; lower neck and underparts black, often hint of paler barring on flanks and undertail-coverts, pale yellow to buffish thighs streaked or spotted black; underwing-coverts buffish; medium-long bill almost pointed, culmen curved, fairly narrow across nostrils, horn-coloured or blue-grey to black, paler lower mandible; iris red or red-brown, orbital ring blue-grey; legs grey. Female has red of malar replaced by black streaks. Juvenile duller than adult, more black around face. Race *ochraceus* is smaller than nominate, less bulky, with less black, head more buffy or cinnamon-tinged, sometimes much black around eye, upperparts more cinnamon-buff with variable black spots and heart-shaped markings, flight-feather bars broader and more cinnamon-buff, underparts more sooty and often with buff-cinnamon edges, flanks usually with much cinnamon to buff, juveniles head sometimes mostly brownish-black; *intercedens* is intermediate in size and plumage, pale areas whitish to buff-white, black below, sometimes some rufous in flight-feathers. Voice. Resonant "tsew tsew tsew-tsew", "wee-wee-week", or well-spaced series of "wheep" notes; also aggressive "tittrrr", raucous "wicket wicket". Drums weakly.

**Habitat.** Humid forest, also savanna and *caatinga*; found at forest edge, in gallery forest, and in orchards. Lowlands.

**Food and Feeding.** Arboreal ants (*Dolichoderus*, *Crematogaster*), also *Camponotus* ants, and termites (Isoptera) are important part of diet; fruits and berries regularly eaten. Generally seen in pairs or small family groups. Mainly arboreal, but also descends to ground to search for insects. Forages on slender branches, with gleaning, probing; also with pecking and hammering, particularly on dead branches.

**Breeding.** Apr-Jun in E Brazil and Oct-Nov in Argentina. Nest-hole in arboreal nest of ants. No other information available.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally not uncommon. Another very little-known woodpecker. Occurs in several protected areas, e.g. Serra da Canastra and Iguaçu National Parks, Rio Doce State Park and Sooretama Biological Reserve (Brazil) and Iguaçu National Park (Argentina).

**Bibliography.** Aleixo & Galetti (1997), dos Anjos (2001), dos Anjos & Schuchmann (1997), dos Anjos *et al.* (1997), Belton (1984), Bencke & Kindel (1999), Brooks *et al.* (1993), Buzzetti (2000), Canevari *et al.* (1991), Capper *et al.* (2000), Chebez *et al.* (1999), Dubs (1992), Figueiredo & Lo (2000), Figueiredo *et al.* (2000), Goerck (1999), Guix *et al.* (1999), Hayes (1995), Madroño, Clay, Robbins *et al.* (1997), Madroño, Robbins & Zyskowski (1997), Meyer de Schauensee (1982), Mikich (1997), Navas & Bö (1988), Olrog (1968), Pacheco & Parrini (2000), Parker & Goerck (1997), de la Peña (1994), Pinto & Camargo (1961), do Rosário (1996), Ruschi (1979), Scott &

Brooke (1985), Short (1972a, 1975, 1985b), Sick (1993), Silveira (1998), Soares & dos Anjos (1999), Stager (1961a), Stotz *et al.* (1996), Tobias *et al.* (1993).

## 162. Cream-coloured Woodpecker

### *Celeus flavus*

French: Pic jaune

German: Strohspecht

Spanish: Carpintero Amarillo

**Taxonomy.** *Picus flavus* P. L. S. Müller, 1776, Cayenne.

Races intergrade extensively, producing many intermediates, and in much of range many individuals impossible to assign to a particular race; geographical limits given are therefore somewhat arbitrary. Races *peruvianus* and *tectricialis* perhaps better merged with nominate. Birds from NE Amazonian Brazil named as race *inornatus*, but inseparable from nominate. Four subspecies recognized.

**Subspecies and Distribution.**

*C. f. flavus* (P. L. S. Müller, 1776) - E Colombia, SW & NE Venezuela and the Guianas S to E Ecuador, W Brazil (S to Mato Grosso) and N Bolivia (Beni).

*C. f. peruvianus* (Cory, 1919) - E Peru.

*C. f. tectricialis* (Hellmayr, 1922) - Maranhão (NE Brazil).

*C. f. subflavus* P. L. Sclater & Salvin, 1877 - E Brazil in Alagoas and S on coast from Bahia to Espírito Santo.

**Descriptive notes.** c. 24-26 cm; 95-131 g (*flavus*), c. 200 g (*subflavus*). Unmistakable; pale yellowish with long crest, black tail, dark wings. Male has bright red malar stripe, sometimes pale-streaked; most of plumage otherwise pale creamy-yellow to buffish or sulphur-yellow, occasionally cinnamon-white, sometimes a few brown feathers or bases visible on head and back (plumage frequently soiled and discoloured, and can acquire browner tone as darker bases appear through abrasion); wing-coverts variable, usually with brown bases, sometimes all brown or rufous-brown, flight-feathers usually brown with rufous-chestnut

inner webs and edges of outer webs, tertiaries usually as back, sometimes darker, rarely with 1 or more dark bars, uppertail blackish-brown, concealed outer feather occasionally with pale bars; underwing brownish, coverts and axillaries creamy-buff; bill slightly chisel-tipped, culmen curved, rather narrow across nostrils, yellowish; iris red or red-brown; legs dark grey to green-grey. Female lacks red on malar. Juvenile as adult, usually somewhat more buff or cinnamon-buff, often with some barring on tertiaries, male soon acquires red tips in malar. Race *peruvianus* is slightly bigger than nominate, rufous in wings typically replaced mostly or entirely by brown; *tectricialis* is similar in size to nominate, but wing-coverts with much brown, flight-feathers with much less rufous; *subflavus* is largest, feathers of mantle and breast have broad brown bases and centres, no rufous in wings. Voice. Distinctive high-pitched laugh, "wutchuk kee-hoo-hoo-hoo", "puer, puer, purr, paw" or similar, with final note lower in pitch; also "kiu-kiu-kiu-kiu", or "wheejah", sometimes repeated, during encounters involving several birds; calls higher-pitched and not so rasping as those of *C. elegans*.

**Habitat.** Humid forest, often near water. Frequents rainforest, such as *várzea* and swamp-forest, forest borders, occasionally gallery forest, mangroves, deciduous woodland, open woodland and second growth; also occurs in other secondary habitats, such as cacao plantations. Lowlands to 700 m, mostly below 400 m.

**Food and Feeding.** Ants (*Crematogaster*) and termites (Isoptera); also eats fruits and seeds. Forages singly, but mostly in pairs or in groups of 3 or 4; not shy. Forages in lower and middle parts of trees, also in canopy; spends much time breaking into nests of arboreal ants and termites. Descends to the ground at times. Not infrequently in open.

**Breeding.** Apr-Jun in Colombia, possibly somewhat earlier in Venezuela. Nest and other details apparently not documented.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally rather uncommon; very common in NE Venezuela; uncommon in Ecuador and Peru; possibly common locally in Brazil. Occurs in Imataca Forest Reserve and El Dorado (Venezuela), Amacayacu National Park (Colombia), Tambopata Reserve (Peru) and Noel Kempff Mercado National Park (Bolivia). Research required on its breeding biology.

**Bibliography.** Allen (1995), Brace *et al.* (1997), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Donahue (1994), Friedmann (1948), Guilherme (2001), Haverschmidt & Mees (1994), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Oren & Parker (1997), Parker & Goerck (1997), Parker *et al.* (1982), Peres & Whittaker (1991), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Robinson & Terborgh (1997), Scott & Brooke (1985), Sick (1993), da Silva (1996), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Tostain *et al.* (1992), Traylor (1958).

## 163. Rufous-headed Woodpecker

### *Celeus spectabilis*

French: Pic à tête rousse

German: Zimtkopfspecht

Spanish: Carpintero Cabecirrufo

**Other common names:** Caatinga Woodpecker (*obrieni*)

**Taxonomy.** *Celeus spectabilis* P. L. Sclater and Salvin, 1880, Sarayacu, Ecuador.

Isolated race *obrieni*, known from only single, female specimen, differs significantly in plumage, and data on habitat indicate major distinction from other races; possibly a separate species, but no further information available. Three subspecies recognized.

**Subspecies and Distribution.**

*C. s. spectabilis* P. L. Sclater & Salvin, 1880 - E Ecuador and NE Peru.

*C. s. exsul* Bond & Meyer de Schauensee, 1941 - SE Peru, extreme W Brazil (W Acre) and N Bolivia (Beni, N Cochabamba).

*C. s. obrieni* Short, 1973 - E Brazil (W Piauí).

**Descriptive notes.** c. 26-28 cm; 111 g (*exsul*). Male has rufous-chestnut head and bushy crest, red malar patch, yellow to cream-buff patch on lower neck side and down side of breast, large area of dull red from above ear-coverts into crest; lower throat to breast black; hindneck to upper back and scapulars creamy-buff to pale cinnamon-yellow with very broad black bars, lower back to uppertail-coverts yellow-buff to cinnamon-buff, occasionally with a few black streaks; black wing-coverts

edged and narrowly barred cream-buff; brownish-black primaries with rufous at base, inner primaries becoming more rufous, secondaries and tertials wholly rufous-chestnut with black tips, shorter tertials usually barred black; uppertail black, concealed outer feather sometimes pale-barred; breast side and rest of underparts cream-buff to pale cinnamon-buff, black of breast breaking up into heavy bars, more as chevrons on flanks and lower underparts; underwing rufous-cinnamon, coverts black-barred cinnamon-buff; bill chisel-tipped, culmen slightly curved, relatively broad across nostrils, pale yellowish or greyish-ivory; iris

deep red-brown; legs olive-green to greyish. Female lacks red on head, but may show trace in crest. Juvenile as adult, but much blackish colour around front of head, more red in crown area, bill darker. Race *exul* resembles nominate, but underpart barring very variable with individual, ranging almost to extremes of other two races, though most commonly less barred below than nominate, with heart-shaped or chevron markings below black breast patch, a few spots on belly and bars on flanks; female *obrieni* (male unknown) is smaller, almost unmarked above (a few bars on mantle), wing-coverts creamy-buff with only small central marks, tertials creamy-buff with irregular black spots, belly unmarked, underwing-coverts unbarred, small outer rectrix pale buffish with black markings. VOICE. Loud squealing "skweeah" followed by bubbling "kluh-kluh-kluh-kluh". Drums on hollow bamboo.

**Habitat.** Inhabits humid tropical forest, especially along rivers and on river islands. Regularly found in bamboo (*Chusquea*, *Guadua*) thickets in Peru, and also strongly associated with bamboo in W Brazil; in Ecuador, favours areas with *Cecropia* trees and cane (*Gynerium*) understorey, as well as *Heliconia*. Occurs in lowlands, up to c. 300 m. Sole specimen of *obrieni* was apparently collected from very different habitat: dry *cerrado* mixed with arid scrub with stunted thorny trees (*caatinga*).

**Food and Feeding.** Contents of diet not recorded to date, although probably feeds on ants, among other items. Forages singly or in pairs, from dense undergrowth up to middle and upper levels of forest. Also descends to ground to work over fallen logs. Probes on trunks and branches, e.g. of *Cecropia*; pecks rather forcefully, and more frequently than most of its congeners, except possibly *C. torquatus*. Observed pecking at horizontal bamboo stems, at heights of 3-10 m, in W Brazil.

**Breeding.** Rather little information available. In Peru, male and female with enlarged gonads collected in Jun, two females in breeding condition taken in Aug. Only two nests found to date, both in SE Peru: one in Jun, 2-8 m up in dead snag with broken-off top, in area of *Guadua* spiny bamboo, hole a vertical oval 12 cm x 10 cm, entrance tunnel sloping upwards, cavity 24 cm deep, incubation suspected but pre-hatch predation thought likely; the other at 1-75 m in a *Cavanillesia* tree with *Heliconia* and *Guadua* understorey, situated in hole 15 cm x 9-3 cm, containing one chick, which was fed solely by male.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare generally; appears to be not uncommon in W Brazil. In SE Peru, 3-4 territories located in c. 150 ha of bamboo habitats surveyed. Regularly recorded in Manu Wildlife Center and Tambopata Research Center (Peru). Rediscovered in Ecuador, at Sacha Lodge, in 1994, after absence of records since 1965; subsequently observed in that country at La Selva, near Pompeya, at Yuturi and at Kapawi Lodge. Very poorly known species; field study and surveys required to determine its true status, as well as its ecology and breeding habits. Race *obrieni* from E Brazil has not been observed in the wild since the holotype was collected, in 1926; fieldwork in 1980 failed to relocate it, and it has to be assumed either that the taxon is extinct or that it represents a highly aberrant form of another species. In view of this species' apparently strict habitat requirements and its low density and general scarcity, it probably merits the conservation status of Near-threatened.

**Bibliography.** Allen (1995), Angehr & Auca (1997), Brace *et al.* (1997), Butler (1979), Clements & Shany (2001), Donahue (1994), Kratter (1997, 1998), Lloyd (2000), Meyer de Schauensee (1982), Olrog (1968), Parker *et al.* (1982), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely *et al.* (1998), Rodner *et al.* (2000), Short (1973b, 1985b), Sick (1993), Stotz *et al.* (1996), Taylor (1995), Terborgh *et al.* (1984), Traylor (1958), Whittaker & Oren (1999).

## 164. Ringed Woodpecker

### *Celeus torquatus*

French: Pic à cravate noir

German: Schwarzbrustspecht

Spanish: Carpintero Pechinegro

**Taxonomy.** *Picus torquatus* Boddaert, 1783, Cayenne.

Named race *angustus* (R Tapajós, Brazil) regarded as synonymous with *occidentalis*, which intergrades with nominate. Three subspecies recognized.

**Subspecies and Distribution.**

*C. t. occidentalis* (Hargitt, 1889) - NE Ecuador, SE Colombia and W & C Amazonian Brazil E to S Venezuela, and S to E Peru, N Bolivia and Mato Grosso.

*C. t. torquatus* (Boddaert, 1783) - E Venezuela and the Guianas S to Pará in NE Brazil.

*C. t. tinunculus* (Wagler, 1829) - E Brazil (SE Bahia, Espírito Santo).

**Descriptive notes.** c. 26-28 cm; 107-124 g (*torquatus*), c. 134 g (*occidentalis*). Male has broad red band from malar region to lower edge of ear-coverts; rest of head, including bushy crest, hindneck, chin and upper throat pale rufous-tinged cinnamon, occasionally hint of reddish on forehead and side of crest; black lower throat, black line from rear malar joining black of breast and upper mantle; lower mantle to uppertail-coverts, including wing-coverts and tertials, rufous-brown, sometimes a few black feathers in lower mantle, usually black sub-terminal bars or V-shaped marks on coverts and 1 or 2 (or more) bars on tertials; flight-feathers

barred black and rufous, rufous more extensive on secondaries; uppertail rufous, narrowly barred black, broader black tip; lower breast to vent plain cinnamon-buff; underwing cinnamon-buff, faint barring on primaries; long bill almost straight, chisel-tipped, relatively broad across nostrils, grey to yellowish-grey or dull olive-brown; iris red to red-brown or brown; legs dark grey. Female lacks red on head. Juvenile as adult, but much black on front of head, more barred. Race *occidentalis* has darker head more cinnamon-tinged, more barred above, but variable, bars sometimes rather weak, lower breast to undertail-coverts much whiter and barred; *tinunculus* is like previous, but head paler, upperparts brighter rufous and more heavily barred, outer tail feathers mostly black, more strongly barred below and on underwing. VOICE. Series of 3-5 loud whistled "kleee", "kuu" or "deeee" notes, evenly pitched.

**Habitat.** Tall humid forest, including rainforest, *terra firme* forest, *várzea* forest, gallery forest; also tall second growth and clearings. Mostly in lowlands, from 100 m to 500 m; to 725 m in Peru.

**Food and Feeding.** Ants and seeds recorded in diet. Singly or in pairs, or in loose groups of up to 5 birds; frequently associated with mixed-species flocks in some areas (in N of range), less often in others (e.g. Ecuador). Forages inconspicuously, mainly at low to medium heights, from understorey to subcanopy; apparently confined more to middle and upper levels in W of range. Moves along larger limbs and trunks. Feeding techniques include gleaning from bark, and hammering into arboreal termitaria.

**Breeding.** No details known.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to rare; uncommon in Venezuela; scarce to uncommon or rare in Ecuador; fairly common but local in Peru. Isolated race *tinunculus*, restricted to forest remnants of E Brazil in Bahia and Espírito Santo, is regarded as endangered. Observed at Emerald Towers and at Timberhead (Guyana). In Brazil, present in Rio Cristalino Private Reserve. In Peru, occurs in Tambopata Reserve and Manu National Park, is regularly seen in Iquitos region, and recorded at Lago Sandoval. In Ecuador, most numerous in lowlands well E of Andes, being absent from areas closer to the mountains. A very poorly known species; in need of research on its diet and feeding, and on its breeding requirements and biology.

**Bibliography.** Allen (1995), Boesman (1995), Butler (1979), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Donahue (1994), Dubs (1992), Haverschmidt & Mees (1994), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Oren (1992), Parker *et al.* (1982), Peres & Whittaker (1991), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely *et al.* (1998), Sharpe *et al.* (2001), Short (1985b), Sick (1993), da Silva (1996), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Teixeira *et al.* (1988), Terborgh *et al.* (1984), Thiollay & Jullien (1998), Tostain *et al.* (1992).

PLATE 43

inches 7  
cm 18

## Tribe CAMPEPHILINI

Genus *DRYOCOPUS* Boie, 1826

## 165. Helmeted Woodpecker

*Dryocopus galeatus*

French: Pic casqué German: Wellenohrspecht Spanish: Picamaderos Caricanelo

**Taxonomy.** *Picus galeatus* Temminck, 1822, Brazil. Monotypic.**Distribution.** E Paraguay, NE Argentina (Misiones) and SE Brazil (São Paulo, Paraná and Santa Catarina; probably extinct in Rio Grande do Sul).**Descriptive notes.** c. 27–28 cm; 124 g. Male has red head and long crest, sometimes with buff or black feather bases showing through, forehead, lores and ear-coverts more cinnamon, ear-coverts thinly dark-streaked or barred; black neck, white stripe from lower rear edge of ear-coverts down neck side to upper breast side; rusty-cinnamon chin and throat, lower throat usually barred dark; black to brownish-black mantle, scapulars and upper back, cream-buff lower back to uppertail-coverts (latter very long) often tinged pale cinnamon, sometimes a few darker bars on middle back, occasionally also rump; wings brownish-black, inner flight-feathers with cinnamon bases; uppertail black; blackish upper breast barred cinnamon, whitish to cinnamon-buff central breast to undertail-coverts entirely barred black; underwing grey-brown, cinnamon coverts and inner wing, coverts variably barred black; fairly long bill slightly chisel-tipped, culmen curved, rather broad across nostrils, grey to blue-grey, paler ivory-coloured tip; iris brown; legs dark grey. Female has slightly smaller bill than male, somewhat longer wings and tail, less red on face. Juvenile little known; browner, less black, than adult, with less red on crown, grey ear-coverts, more extensively barred. Voice. Loud ringing series of 3–12 “keer” notes, shorter and slower than that of *D. lineatus*, probably associated with territorial behaviour; less loud, mournful “tu-hu-u-u-u-u” series, of which “kee-doo-doo-doo-doo-doo” probably a variant, as contact between pair-members; soft “chic” notes; intimate calls between partners “che-che-che”. Drumming soft, pattern uniform, roll 1–5 seconds long.**Habitat.** Tall lowland and montane forest, Primary forest, disturbed and even logged (primary) forest, so long as not severely affected; recorded also in gallery forest and small patches of degraded forest, usually near large tracts of intact forest. Association with bamboo probably accidental. In lowland valleys, and in cloudforest to c. 800 m.**Food and Feeding.** Feeds on beetle larvae living beneath bark. Mostly found singly or in pairs. Forages in middle storey at 14–15 m in forest interior; also lower, down to 2–5 m, at forest edge. Searches branches of a broad range of sizes (2–30 cm in diameter), including those covered with mosses and lichens. Obtains prey by removing bark, often combined with pecking, probing beneath bark, and some gleaning; hammers only occasionally, with little persistence, and does not make large cavities.**Breeding.** Nests found in Sept–Oct; season probably to Feb. Nest seems to be surprisingly low down, at 2–3 m, in tree. No further details known.**Movements.** Resident.**Status and Conservation.** VULNERABLE. Total population estimated at no more than 10,000 individuals. Known from only a small area of at most 24,000 km<sup>2</sup>; probably extinct in Rio Grande do Sul, where formerly occurred in the coastal NE. Occurs in numerous protected areas throughout its range: in Paraguay, in Estancia San Antonio Private Nature Reserve, Mbaracayú Forest Nature Reserve, Itabó Private Reserve, San Rafael National Park, Caaguazú National Park, Golondrina Private Reserve, and Cerro Corá National Park; in Brazil, Intervalas State Park, Ilha do Cardoso State Park, and Iguaçu National Park; and in Argentina, Igazú National Park (4 pairs located), Esmeralda Provincial Reserve, Uruguá-i Provincial Park, Caa Porá Private Reserve, Moconá Provincial Park, and Campo San Juan Protected Reserve. Legally protected in Brazil. Preferred habitats have suffered extensive clearance, fragmentation and degradation over many decades, and it seems reasonable to assume that this picid has declined quite significantly since the 1950’s. Nevertheless, it may have been under-recorded in recent years, since it is not easy to locate except during the brief period of the year when it calls. Intensive searches have revealed its presence in both lowland and montane forest, also in selectively logged areas, gallery forest, and even in small patches of degraded forest. Numerous sightings since mid-1980’s, including a pair in 1998 in Brazilian state of Santa Catarina, where the species had not been seen since 1946. These encouraging reports suggest that this woodpecker is not so scarce as was previously believed, but continuing forest destruction remains a serious threat. Further studies required, aimed at clarifying its distribution and status.**Bibliography.** Anon. (1995c, 1998f), Belton (1984), Blendinger (1998), Brooks *et al.* (1993), Canevari *et al.* (1991), Chebez (1986, 1994, 1995), Chebez *et al.* (1999), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Gliesch (1930), Guix *et al.* (1999), Hayes (1995), King (1978/79), Knox & Walters (1994), Lowen, Barrina *et al.* (1996), Lowen, Clay *et al.* (1995), Lucero & Alabarce (1980), Madroño & Esquivel (1995), Madroño, Clay & Hostettler (1997), Naka *et al.* (2000), Navas & Bo (1993), Parker & Goerck (1997), Paynter (1985, 1989), Paynter & Traylor (1991), de la Peña (1994), Pinto (1938b), Pinto & Camargo (1955), Short (1985b), Shuker (1993), Sick (1985, 1993), Stattersfield & Capper (2000), Storer (1989), Stotz *et al.* (1996), Willis (1987), Willis & Oniki (1993).

## 166. Pileated Woodpecker

*Dryocopus pileatus*

French: Grand Pic German: Helmspecht Spanish: Picamaderos Norteamericano

**Taxonomy.** *Picus pileatus* Linnaeus, 1758, America = South Carolina.Forms a superspecies with *D. lineatus* and *D. schulzi*. Little geographical variation, mostly clinal: proposed races *pinus* (British Columbia) and *floridanus* (Florida) considered not to differ significantly from, respectively, *abieticola* and nominate. Two subspecies recognized.**Subspecies and Distribution.***D. p. abieticola* (Bangs, 1898) - S British Columbia E across S Canada to Nova Scotia, S to NW & CE California, C Idaho, W Montana, C Saskatchewan, SE Iowa and about Virginia.*D. p. pileatus* (Linnaeus, 1758) - SE USA, from approximately Illinois E to Virginia and S to SE Texas and Florida.**Descriptive notes.** 40–48 cm; 250–340 g (*abieticola*). Large. Male has buffish nasal tufts, bright red forehead, crown and long crest, narrow white stripe behind eye, black band from upper lores through eye to nape side, white band from base of upper mandible back to rear neck side and continuing broadly down side of neck to upper flank; dark red malar stripe black at rear, joining with black of foreneck; white chin and upper throat, sometimes with greyish streaks; upperparts and wings black, small white tips on outer primaries, larger area of white at bases of primaries and outer secondaries, alula and primary coverts variably edgedwhite; uppertail black, initially with small white tips; apart from white upper flanks, grey-black to blackish below, narrowly barred grey on lower flanks, sometimes also on belly; underwing white, primary coverts barred blackish, broad black tip and trailing edge; in worn plumage, black areas become browner; medium-length bill broad, chisel-tipped, culmen slightly curved, slate-grey, blackish tip; iris pale yellow, orbital skin greyish-olive; legs dark blue-grey to blackish. Female is slightly smaller, shorter-billed than male, has forehead and forecrown black, sometimes with some brown-buff tips and often also some red tips, malar fully black. Juvenile duller, more sooty, than adult, throat greyish or grey-streaked, eyes blue-grey, male with orange-red tips on forehead, crown and small crest, faint red tips in malar, female with grey-brown forehead to crown sides and no red in malar. Race *abieticola* is slightly bigger than nominate, has longer bill, some birds in extreme W also with grey throat. Voice. Single or repeated “wuk”, “cuk” or “cac” notes, particularly in flight, as e.g. contact between pair-members, when approaching roosting area, and in series when alarmed, also in fast series; higher-pitched calls given on landing; mewing calls associated with sexual activities; various repeated “waak”, “woick woick” and “wok” notes during encounters, also associated with visual displays; low-pitched “waaa”, sometimes in irregular series, as intimate call; squeaking to churring calls by young. Drumrolls distinctive, loud, with full timbre, accelerate at end, usually 1–2 seconds long, 1–2 per minute; loud taps from inside nest when partner approaches; double raps in context of copulation and hole demonstration.**Habitat.** Coniferous and deciduous forest, and mixed forest, from rather open deciduous to dense mature coniferous stands. Mature and extensive stands favoured. Occurs also in second growth having some large trees and at least 5 years old; enters suburbs and parks. Data from Oregon and elsewhere suggest that stands over 70 years old, and often close to water, preferred for nesting, and that riparian woodland and stands older than 40 years preferred for foraging. Juniper (*Juniperus*) woodland and pure pine monocultures are avoided. From sea-level to above 1500 m in E mountains, to c. 2300 m in W.**Food and Feeding.** Mainly ants, principally carpenter ants (*Camponotus*), but *Crematogaster* and *Formica* also recorded; beetle larvae also taken throughout year. Also other insects, including termites (Isoptera), caterpillars. Fruits, e.g. cherries, dogwood (*Cornus*), wild grapes (*Vitis*) and similar, and berries, e.g. holly (*Ilex*), various *Rhus* species, *Smilax*, hackberry (*Clethra*) and others, also eaten, as well as nuts (e.g. acorn, pecan). Importance of fruits varies locally, and can comprise almost a third of diet. Fruits and suet accepted at feeders. Mostly singly; paired birds keep loose contact. Not very shy. Feeds at all levels, including on ground, where it works over fallen logs or attacks anthills. Dead wood preferred for foraging. Pecking and hammering comprise 60–95% of foraging activities in non-breeding season; often hammers for long periods at one spot. Scaling of bark also a very important technique. Probing and, less so, gleaning are minor foraging methods, used most in breeding season and then comprising almost 20% of foraging activities. Plucks fruit from very thin branches.**Breeding.** Laying from Apr in S, May–Jun in N and at higher altitudes; courtship from Feb. Displays include crest-raising, wing-spreading, also head-swinging with bobbing and head-raising, also flutter-aerial display. Usually new nest excavated each year, by both sexes, taking 3–6 weeks, at 4–30 m (mostly 6–12 m) in main trunk of dead tree, or old living tree, with breast-height diameter 33–91 cm (usually exceeding 40 cm), frequently conifer but also deciduous (e.g. *Quercus*, *Acer*, *Ulmus*); sometimes in utility pole; hole dimensions 11–12 cm tall, 7.5–9 cm wide, cavity depth c. 30–45 cm; territory defended by both sexes. Clutch 1–6 eggs, usually 2–4, average 3–8, larger clutch sizes in N populations; incubation by both sexes, period c. 15–16 days, only male incubating at night; both parents feed chicks, by regurgitation, both also brood them and share in nest sanitation, male broods more than female, partners take about equal share of feeding duties; fledging period 24–28 days, sometimes up to 31 days in S; fledged brood accompanied by both parents or divided between them, fed for several months, family group remaining intact until Sept or later. Mean brood size at fledging 2.0 young in Montana, 2.26 in Oregon, 2.14 in Louisiana; 83% of nests produced at least 1 young in Oregon. First breeds at 1 year. Recorded longevity in wild over 9 years.**Movements.** Chiefly resident. Possibly some short-distance movement or wandering; in montane areas may move to lower elevations after breeding.**Status and Conservation.** Not globally threatened. Not very common, and generally rather local. Estimates of density in first half of 20th century include 1 pair/67 ha in Florida and 1 pair/43–260 ha in Louisiana; approximate estimates in 1980’s and 1990’s range from 0.4–4.1 territories/100 ha in Missouri to 1 pair/160–220 ha in California and 1 pair/356 ha in Oregon. Large home ranges, c. 480 ha post-breeding, but can overlap by up to 30%. Predation can have significant adverse effect on populations; habitat alteration can eliminate nesting and foraging areas. Suffered greatly in 19th century during period of extensive land clearance, but has regained much of its former range from c. 1920 onwards. Has increased in most of range since mid-1960’s. Although a legally protected species, it is sometimes persecuted for its occasional habit of excavating on buildings.**Bibliography.** Aubrey & Raley (1992, 1994), Baitech & Harrison (1997), Beckwith & Bull (1985), Bent (1939), Bonar (1994, 2000), Brown (1978), Bull (1974, 1978, 1981, 1987), Bull & Holthausen (1993), Bull & Jackson (1995), Bull & Meslow (1977, 1988), Bull & Snider (1993), Bull, Beckwith & Holthausen (1992), Bull, Holthausen

## 167. Lineated Woodpecker

### *Dryocopus lineatus*

**French:** Pic ouentou

**German:** Linienspecht

**Spanish:** Picamaderos Listado

**Other common names:** Black-mantled Woodpecker (*erythrops*)

**Taxonomy.** *Picus lineatus* Linnaeus, 1766, Cayenne.

Forms a superspecies with *D. pileatus* and *D. schulzi*. Interbreeds with latter. Large degree of individual variation exists among all populations. Race *erythrops*, previously regarded as a separate species, is perhaps only a variable morph. Additional described races are *obsoletus* (Sonora), *petersi* (Tamaulipas), *mesorhynchus* (Costa Rica), *nuperus* (Santa Marta, in N Colombia), *improcerus* (Bahia, in E Brazil) and *fulcitus* (Chaco, in Argentina), all considered insufficiently differentiated to be accepted. Five subspecies recognized.

**Subspecies and Distribution.**

*D. l. scapularis* (Vigors, 1829) - W Mexico (S from Sonora).

*D. l. similis* (Lesson, 1847) - E & S Mexico S to NW Costa Rica.

*D. l. lineatus* (Linnaeus, 1766) - E & S Costa Rica to W Colombia and E to Trinidad, the Guianas and NE & E Brazil (Maranhão, Bahia), S to E Peru, N Paraguay and São Paulo.

*D. l. fuscipennis* P. L. Slater, 1860 - W Ecuador and NW Peru.

*D. l. erythrops* (Valenciennes, 1826) - E Paraguay, N & NE Argentina (E Salta, Misiones, Corrientes) and SE Brazil (Espírito Santo and São Paulo S to Rio Grande do Sul).

**Descriptive notes.** c. 30-36 cm; male 204-217 g, female 186-213 g (*lineatus*), 150-164 g (*similis*), male 182-264 g (*erythrops*). Male has bright red forehead, crown and crest, often some dark grey feather bases visible, blackish area from upper lores back across ear-coverts to hindneck (rarely, very thin white line behind eye), white stripe from yellowish loreal area to lower rear border of ear-coverts and down neck side, black malar stripe with much red in fore part, expanding at rear and joining with black of breast; white chin and throat with variable, often heavy, black streaking; black hindneck and upperparts, white outer webs of outer

scapulars (exceptionally, scapulars all black), white area on bases of inner webs of flight-feathers, usually small whitish area on carpal; uppertail black; black breast, black occasionally extending to belly, greyish-buff to whitish belly, flanks and undertail-coverts variably barred brownish-black, in N of range more buff and bars more irregular; underwing blackish, coverts and bases of flight-feathers white or pale buff, sometimes small black patch on primary coverts; in worn plumage, all black areas browner, feather bases more visible; long bill chisel-tipped, culmen slightly curved, broad across nostrils, grey to grey-black, paler lower mandible, usually dark tip; iris white to pale orange, orbital skin brown; legs grey, tinged green, blue or yellow, sometimes olive. Differs from *D. schulzi* mainly in barred underparts, pale eyes. Female is somewhat smaller than male, has forehead, forecrown and malar all black. Juvenile duller than adult, black areas browner. Breast more extensively dark, barring below more obscure and less regular, flight-feathers with obvious white tips, eyes brown, head pattern as that of respective adult or, rarely, crown more yellow than red, male with less red in malar. Race *scapularis* is smaller than nominate, but slight size increase clinally to N, lacks white stripe from lores to neck side, bill pale; *similis* is larger than previous, ground colour of underparts buff; *erythrops* is larger than S nominate, dark-billed, occurs in 2 forms, S birds lack white scapular lines. N birds may or may not have these markings, exceptionally only partial white on scapulars, population in Iguazú area of N Misiones (Argentina) often with much rufous in ground coloration below; *fuscipennis* is smaller than nominate, dark-billed, distinctly brown, upperparts deep brown, breast sooty, belly to undertail-coverts buffish with obscure brown barring, wing and tail shafts pale, undertail glossed yellow-brown on outer feathers. **VOICE.** Call note a loud sharp "pik"; rattle as "kip-whurr", "pik-urr-r-r", "ik-rrrr", "cuchrrrrrrrr", or "k' rroo"; common call loud, explosive, far-carrying "wicwic-wicwic", "wuk wuk wuk", "kyah-yik-yik-yik", or "weep weep weep weep", up to c. 30 notes, dying at end; also woodpecker-like "wer wer wer". Both sexes drum, loudly, making 5-8 slow taps followed by long accelerating tattoo.

**Habitat.** Humid, transitional and moderately dry areas; generally avoids xerophytic areas or marshes, but frequents mangroves. Occasionally found in dense forest or tall rainforest, but more open areas preferred generally; especially numerous around new clearings and at forest edge. Enters pine (*Pinus*) forest and gallery forest in drier areas, as well as thorn-scrub. Also occurs in shaded gardens, moriche groves (Venezuela), on trees in pastures and cultivations, and particularly in second growth with sufficiently large trees (e.g. fast-growing *Cecropia*). Lowlands, foothills, and even higher, to 1200-2100 m.

**Food and Feeding.** Known to consume beetles and their wood-boring larvae, ants (*Crematogaster*, *Camponotus*, *Azteca*) and their brood, caterpillars, orthopteran egg cases; also takes fruit and seeds (*Heliconia*). Often in pairs, also in family groups of 4-6 birds; single individuals may join mixed-species flocks, e.g. with antwrens (*Myrmotherula*). Active and noisy; easily alarmed. Forages at all heights; also descends to ground, where tosses aside leaves in search of food. Readily visits isolated trees in open areas. Forages on trunks and large limbs, occasionally also on telephone poles; males prefer larger branches than those used by females. Hammering and pecking deeply and persistently into both live and rotting wood predominate among feeding techniques; probing into excavations also common. Particularly adept in securing ants and their brood in *Cecropia*. Frequently pries up and scales pieces of bark from dead trunks and branches. Visits well-foliated parts of the crown in

search of fruits, even on very thin twigs. May feed at one spot for 10-15 minutes, then fly long distance to another.

**Breeding.** Mar-Apr in Panama, Apr-May in Belize, and Feb-Apr in Trinidad and Surinam; birds in breeding condition in Jan-Feb in Colombia; season Jul-Nov in S. Remains paired throughout year. Display with crest-raising. Nest excavated in dead tree or top of stub of small girth (18-23 cm), sometimes up to 27 m up in very tall tree, sometimes rather low down, to c. 2 m; toucans (Ramphastidae) are important hole competitors. Clutch 2-3 eggs; incubation and fledging periods not documented; chicks fed by both parents, by regurgitation.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common, and widespread, throughout most of range; uncommon to fairly common in Ecuador and Peru. Occurs in numerous protected areas throughout its extensive range, e.g. Santa Rosa National Park (Costa Rica), Guatopo National Park (Venezuela), Asa Wright Nature Centre (Trinidad) and Serra do Cipó National Park (Brazil). Preference for open habitats means that it benefits from clearance of forest; survives well in degraded areas. No known threats.

**Bibliography.** dos Anjos & Schuchmann (1997), Belton (1984), Binford (1989), Brooks, D.M. (2000), Brooks, T.M. *et al.* (1993), Buzzetti (2000), Canevari *et al.* (1991), Capper, C.J., Madroño, Mazar Barnett, Burfield *et al.* (2001), Capper, Esquivel *et al.* (2000), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Contreras *et al.* (1990), Figueiredo & Lo (2000), Goerck (1999), Guix *et al.* (1999), Haverschmidt & Mees (1994), Hayes (1995), Hayes & Samad (1998), Heisler (1994), Herklots (1961), Hernández *et al.* (1995), Hilty (1997), Hilty & Brown (1986), Howell & Webb (1995), Kilham & O'Brien (1979), Marini (2001), Mauricio & Dias (1998), Mayr & Short (1970), Melo-Júnior (2001a), Meyer de Schauensee & Phelps (1978), Monroe (1968), Parker & Goerck (1997), de la Peña (1994), Pople *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Robinson (1997), Robinson & Terborgh (1997), Rowley (1966, 1984), Short (1975), Sick (1993), Skutch (1969a), Slud (1964), Stager (1961a), Stiles (1985), Stotz *et al.* (1997), Tostain *et al.* (1992), Wetmore (1968a), Willis (1980).

## 168. Black-bodied Woodpecker

### *Dryocopus schulzi*

**French:** Pic lucifer

**German:** Schwarzbauchspecht

**Spanish:** Picamaderos Chaqueño

**Other common names:** White-shouldered Woodpecker ("*shiptoni*"; Chaco Woodpecker ("*major*")

**Taxonomy.** *Phloeotomus Schulzi* Cabanis, 1883, Tucumán, Argentina.

Forms a superspecies with *D. pileatus* and *D. lineatus*. Hybridizes with latter. Forms described as "*D. shiptoni*" and "*D. major*" are only variants or colour morphs. White scapular line more prevalent among N birds, and S birds average minimally smaller than others, but differences insufficient to justify subspecific separation. Monotypic.

**Distribution.** S Bolivia (Santa Cruz, Tarija), C Paraguay and S to NC Argentina (S to Córdoba and San Luis).

**Descriptive notes.** 29-30 cm. Male has yellowish-buff nasal tufts, bright red forehead to nape and long crest, sometimes some white feather bases showing through, grey ear-coverts often spotted white, usually very thin white supercilium behind eye (more or less invisible in field), white stripe from lores back through ear-coverts expanding just before nape, continuing down neck side; red malar stripe becoming black at rear, joining with black of breast; white to greyish-white chin and upper throat occasionally with very fine brown to blackish streaks (streaks rarely visible); hindneck and entire upperparts black, scapulars all black

(most of S population) or with white on outer webs meeting white of neckstripe (most of N population, some S birds), or with partial white forming broken line (a few throughout range); black wings, white at bases of flight-feathers, sometimes whitish area at margin of carpal region; uppertail black, white shafts, sometimes white feather tips when fresh; black to brownish-black below, often very narrow obscure yellowish barring on lower flanks and belly (rarely, barring reaching upper flanks, even across entire belly); underwing blackish, axillaries and coverts whitish, primary coverts with irregular large black patch, variable, patch can be almost absent; in worn plumage, black areas browner, pale or dark feather bases more obvious on head and other areas; long bill straight, slightly chisel-tipped, broad across nostrils, pale ivory-white, darker culmen and base; iris deep brown to red-brown, orbital skin grey to blackish; legs dark grey. Female has slightly shorter bill than male, malar lacking red, lower forehead blackish, sometimes white specks in forecrown, but red often extends well down forehead. Juvenile duller and browner than adult, more flank barring, forecrown often with white spots, head pattern as respective adult. **VOICE.** Common call a loud "wic wic wic wic wic", slower and generally shorter than that of *D. lineatus*; harsh rattle, "ti-chrr", heard much less frequently; descending "krrrrrr" repeated when disturbed near nest. Drums like *D. lineatus*, possibly slightly shorter rolls.

**Habitat.** Xeric woodland and savanna of the Chaco with *Lithrea*, *Celtis*, acacias, carob (*Prosopis*) and cacti, and transitional habitats to mesic montane forest with alder (*Alnus*) and *Tipuana*. More humid Chaco areas possibly of marginal importance. Occurs up to 1500 m in foothills of Andes, in EC Bolivia and NW Argentina.

**Food and Feeding.** Diet not described. Forages singly or in pairs, occasionally in family groups of 5-6 birds, apparently on trunks and main limbs. Techniques include pecking, hammering and probing.

**Breeding.** Oct-Dec, possibly Mar. Nest-hole built in dead tree or utility pole; one in Argentina (Córdoba), in Dec, was c. 4 m above ground in dead limb of *Schinopsis haenkeana*, entrance hole 8 cm wide and 6 cm high, cavity depth c. 40 cm, contained 2 well-grown chicks. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Generally rare. Has declined in many areas, and seems to have been reduced to two main populations, one in Argentine provinces of Córdoba and San Luis, the other in C Paraguayan Chaco. Apparently few survive elsewhere, where expansion of agriculture and cattle-raising has resulted in extensive clearance of woodland, and the planting of exotic trees. Details of this woodpecker's habitat preferences are not yet fully understood; further research required.

**Bibliography.** Brooks (1997), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Contreras *et al.* (1990), Degan & Popovici (1973), Hayes (1995), Heredia *et al.* (1999), Madroño (1995), Madroño & Pearman (1992), Mazar Barnett & Pearman (2001), Narosky & Yzurieta (1993), Nellar (1993), Nellar & Fraga (1999), Norez *et al.* (1983), de la Peña (1994), Remsen & Traylor (1989), Remsen *et al.* (1986), Short (1975, 1985b), Stattersfield & Capper (2000), Stotz *et al.* (1996).

## 169. White-bellied Woodpecker

*Dryocopus javensis*

**French:** Pic à ventre blanche **German:** Weißbauchspecht **Spanish:** Picamaderos Ventriblanco  
**Other common names:** Great Black/White-bellied Black Woodpecker; Indian Great Black Woodpecker (*hodgsonii*)

**Taxonomy.** *Picus Javensis* Horsfield, 1821, Java.

Forms a superspecies with *D. hodgei*, and sometimes considered conspecific. Proposed race *buettikoferi* (Nias I) appears indistinguishable from nominate; *esthloterus* (N Luzon, in Philippines), supposedly with thinner bill and less white on head, is not safely separable from *confusus*. Race *philippinensis* frequently misspelt “*philippensis*”. Fourteen subspecies recognized.

**Subspecies and Distribution.**

*D. j. hodgsonii* (Jerdon, 1840) - peninsular India in Western Ghats, S Madhya Pradesh, and Orissa to N Andhra Pradesh.

*D. j. forresti* Rothschild, 1922 - montane N Myanmar and adjacent SW China (SW Sichuan, NW & S Yunnan).

*D. j. richardsi* Tristram, 1879 - Korea; extinct on Tsushima I (Japan).

*D. j. feddeni* (Blyth, 1863) - Myanmar (except N), most of Thailand, and Indochina.

*D. j. javensis* (Horsfield, 1821) - S Thailand S to Sumatra and Nias I, Java, Bali, and Borneo and associated islands, including N Natunas.

*D. j. parvus* (Richmond, 1902) - Simeulue I (off NW Sumatra).

*D. j. confusus* (Stresemann, 1913) - Luzon (N Philippines).

*D. j. mindorensis* (Steere, 1890) - Mindoro.

*D. j. hargitti* (Sharpe, 1884) - Palawan.

*D. j. philippinensis* (Steere, 1890) - Panay, Masbate, Guimaras, Negros.

*D. j. cebuensis* Kennedy, 1987 - Cebu (probably extinct).

*D. j. pectoralis* (Tweeddale, 1878) - Samar, Calicoan, Leyte, Panaon, Bohol.

*D. j. multilunatus* (McGregor, 1907) - Basilan, Dinagat, Mindanao.

*D. j. suluensis* (W. Blasius, 1890) - Sulu Is.

**Descriptive notes.** 40-48 cm; 197-347 g. Large to very large woodpecker. Male has deep red forehead to nape and crest, fairly broad red malar stripe; rest of head, entire upperparts, including wings and tail, and chin to lower breast black, white streaks on ear-coverts (especially at rear), neck side and chin to throat, primaries tipped white when fresh, small patch of cream-white at bases of inner webs; belly creamy, occasionally narrow creamy bars on lower breast side, usually black bars on flanks and ventral area, black undertail-coverts; underwing grey-black, coverts creamy, black carpal patch; undertail greyish; long bill broad-based,

chisel-tipped, culmen curved, black to grey-black, sometimes pale greenish lower mandible; iris yellow, orbital skin grey; legs dark grey or blue-grey. Female is slightly less bulky than male, has forehead and forecrown black, malar area black with white streaking. Juvenile duller, browner, throat paler, often trace of white on rump, eyes grey, male with red forehead and crown mottled with black and white, only little red in malar. Races differ from nominate in size and plumage, most having white on rump; *hodgsonii* has larger all-blackish bill, shorter wing and tail, white rump; *forresti* is quite big, with proportionately short tail, has rump white, throat mainly black; *richardsi* is very large, with long bill, white rump, much white at primary bases, male's malar somewhat narrow, female distinctive with head entirely black; *feddeni* is smaller than nominate, with orange-red head colour, white rump, much white on primary bases, usually white-tipped primaries; *parvus* is smallest of all races, has black rump, very dark red on crown, hint of buff barring on ear-coverts, throat and breast; *hargitti* has large white rump, crown colour more orange-red, red malar more extensive, flanks and lower underparts black, pale thighs, base of lower mandible pale greenish-yellow or horn; *mindorensis* is like previous but much smaller, with less white on rump, usually white-tipped primaries, bill wholly blackish; *confusus* is like last but longer-billed, with very little or no white on rump, sometimes black throat with few white spots, sometimes pale lower mandible, male with more extensive red malar; *philippinensis* is larger than previous, has narrow white rump, pale lower mandible, some have black throat with sparse white spots, male with red of malar invading throat and face; *multilunatus* is similar to last but no white on rump, has white streaking on neck sides and ear-coverts, buffish barring on breast, usually white-tipped primaries; *cebuensis* is smaller and shorter-billed than last, has small white patch on lower back; *pectoralis* is fairly distinctive, has black-streaked white throat and rear ear-coverts, pale bars or streaks over breast, more heavily barred flanks, sometimes dark spots on belly, occasionally hint of white on rump; *suluensis* is small, with no white on rump or, rarely, very small patch, normally pale lower mandible. Voice. Loud single “kiyow”, “kyah”, “kiauk” or “keer” call note, slightly lower-pitched and more explosive than similar call of *D. martius*; long calls “kek-ek-ek-ek-ek” or “kiauk kiauk kiauk kiauk”, 3-4 notes per second, some series over 5 seconds long, both in flight and when perched; low “ch-wi” notes between pair-members. Both sexes drum, loud accelerating rolls, slower at beginning than those of *D. martius*, less than 2 seconds long, c. 3 rolls per minute; a low fast tapping at nest.

**Habitat.** Various types of evergreen and deciduous forest, locally also pine (*Pinus*) forest; closed primary forest, forest edge, dry dipterocarp forest, mixed bamboo stands, light secondary forest with large trees. Wet primary forest with many dead and rotting trees often preferred, but readily occupies selectively logged and degraded forest; sometimes forages up to c. 200 m from forest, also appears near cultivations, gardens. In Japan (Tsushima), occurred in dense mature coniferous forest mixed with oaks (*Quercus*) and camphors. Lowlands to 1200 m in India; to 1000 m in most parts of SE Asia and in Greater Sundas, generally below 600 m in Thailand, but above 1400 m and up to 3600 m in NE Myanmar, NW Tonkin and Yunnan; to 1600 m in Philippines, locally (N Luzon) to 2500 m.

**Food and Feeding.** Diet comprises large ants and their brood, termites (Isoptera), beetles and their (large) wood-boring larvae, also other insects, e.g. bees, and Myriapoda. Fruits (e.g. *Cornus*, *Macaranga*, *Olea*) also taken. Usually solitary or in pairs, and groups of 4-6 birds sometimes observed. Forages from lower to upper strata, in tall trees, on small dead stubs, on fallen timber, and on ground, searching among the litter; prefers dead trees, or dead parts of trees. Pecks and hammers, and commonly strips bark; also probes, and pries off pieces of bark and wood; removes large pieces of bark before digging big pits up to 20 cm long and 8 cm deep into the wood. Will spend up to one hour or more at a single favoured feeding site.

**Breeding.** Jan-Mar in India, Feb-May in Myanmar, late Mar to early May in Korea, Dec-Mar in Peninsular Malaysia, Apr-May and Aug-Sept in Greater Sundas, and Mar-May in Philippines. Dis-

plays poorly known, include moderate crest-raising. Nest-hole excavated by both sexes, 4-24 m up in tall stump or tall old or half-dead tree, cavity depth up to 60 cm; male demonstrates intended nest with long series of regular taps. Clutch 2 eggs, in N sometimes 3 or 4 eggs; both parents incubate, period 14 days; both also feed chicks, by regurgitation, female possibly feeding more than male; nestlings fledge after 26 days, accompanied by adults for variable period.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Race *richardsi* CITES I. Local and uncommon throughout range; uncommon to rare and very local in India, most frequent in N part of Western Ghats; uncommon in China; scarce in peninsular Thailand; believed extinct in Singapore but observed at two different sites in 1993, the first since 1988; still reasonably common on Simeulue (*parvus*); scarce to rare in Java and Bali; fairly common to uncommon in Philippines, apparently extinct on Cebu (*cebuensis*). Race *richardsi* rare and endangered in Korea, extinct in Japan (Tsushima). Occurs in many protected areas, such as Panti Forest Reserve (Malaysia), Doi Inthanon National Park (Thailand), Nam Bai Cat Tien National Park (Vietnam), Way Kambas National Park (Sumatra), and Aas Purwo National Park (Java). Occurs at rather low densities; radius of home range c. 2 km. Habitat loss could pose a threat to this species in the longer term.

## 170. Andaman Woodpecker

*Dryocopus hodgei*

**French:** Pic des Andaman **German:** Andamanenspecht **Spanish:** Picamaderos de Andamán  
**Other common names:** Andaman Black Woodpecker

**Taxonomy.** *Mulleripicus Hodgei* Blyth, 1860, Andaman Islands.

Forms a superspecies with *D. javensis*, and sometimes treated as conspecific. Monotypic.

**Distribution.** Andaman Is.

**Descriptive notes.** 38 cm; 156-225 g. Male has crimson forehead, crown and crest and malar area; rest of head, and upperparts, including wings and tail, greyish-black to sooty-black; entire underparts sooty-black; bill blackish; iris pale yellow, orbital skin greyish; legs slaty. Female has red only on hindcrown and crest. Juvenile as adult but duller, browner, eyes grey, male with black and white mixed in red crown feathers, much less red in malar. Voice. Loud chattering “kuk kuk kuk” terminating with whistled “kui”, also loud sharp “kik, kik, kik”; calls differ from those of *D. javensis*. Drumming loud, far-carrying.

**Habitat.** Tall evergreen forest, often rather open. Lowlands.

**Food and Feeding.** Ants. Lives in pairs; also occurs in loose family parties. Forages mainly on trunks of large trees or on main (dead) branches; descends to ground to hunt for ants. Hammers powerfully.

**Breeding.** Jan-Mar. Nest-hole built 6-14 m up in trunk of dead tree or in large branch; 2 eggs; no other details.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in Andaman Islands EBA. Although still common in evergreen forest where large trees remain, recent rapid expansion of human population on the larger islands of Andamans has brought problems. Logging and conversion of forest to agricultural and grazing land likely to become a serious threat. Conservation recommendations include monitoring of the woodpecker's numbers and, if necessary, implementation of measures to prevent further loss of forest habitat.

**Bibliography.** Andreev *et al.* (2001), Collar *et al.* (1994), Curson (1989), Davidar *et al.* (1997), Grimmett *et al.* (1998), Inskipp *et al.* (1996), Sankaran & Vijayan (1993), Stattersfield & Copper (2000), Stattersfield *et al.* (1998), Wheatley (1996).

## 171. Black Woodpecker

*Dryocopus martius*

**French:** Pic noir **German:** Schwarzspecht **Spanish:** Picamaderos Negro  
**Other common names:** Great Black Woodpecker

**Taxonomy.** *Picus martius* Linnaeus, 1758, Europe = Sweden.

Size varies clinally, decreasing from N to S and, in Asia, from E to W; birds from S Europe E to Transcaucasia sometimes separated as race *pinetorum* (slightly smaller than N breeders) and those from E Asia as *reichenowi* (on average larger than W Asian populations), but much overlap occurs in measurements, and racial separation not warranted. Two subspecies recognized.

**Subspecies and Distribution.**

*D. m. martius* (Linnaeus, 1758) - Europe from Spain, France and Scandinavia (N to Arctic Circle), S to Balkans and N Turkey, and E in broad belt across Asian *taiga* (S to Altai Mts, N Mongolia) to Kamchatka, Sakhalin and Japan (Hokkaido, extreme N Honshu), NE China and Korea; also Caucasus and N Iran.

*D. m. khamensis* (Buturlin, 1908) - SW China and Tibet (Qinghai S to NW Yunnan).

**Descriptive notes.** 45-55 cm; 250-370 g. Very large. Male has red central forehead to hindcrown, a few grey feather bases sometimes showing through; rest of plumage black, head and upperparts (especially wing-coverts) glossed dark blue, primaries tinged dark brown, underparts slightly duller and often tinged grey; in worn plumage duller, distinctly grey-tinged below, and red on head mixed

with dark grey; long bill chisel-tipped, very broad-based, culmen slightly curved, pale ivory-white to pale horn, culmen and tip bluish to blackish; iris whitish or yellowish-white, sometimes pale cream-grey; legs dark greyish to blue-grey. Female has forehead and fore-crown glossy black, red only on hindcrown, bill shorter than male's. Juvenile duller, more sooty-black, often with paler (dark grey) throat, red on head duller or paler with larger dark feather bases, male with less red than adult. Race *khamensis* differs from nominate in blacker and more glossy plumage. Voice. Loud "krry-krry-krry" in flight, "ke-yaa" on landing

and when perched; before and during breeding, long series of 10-20 more melodious notes, "kweeekweeekweeekwek-wikwik"; "kiyák" as alarm or in aggression; intimate calls shorter "kyah", or "rriirrirrri". Drumroll long, sometimes over 3 seconds, c. 14 (female) to 17 (male) strokes, rate c. 4 rolls per minute, males drum more frequently; loud rhythmic tapping at nest, by both sexes.

**Habitat.** All types of mature forest, so long as not extremely dense and gloomy; also forest edge. Spruce (*Picea*) and pine (*Pinus*) forests with larch (*Larix*), birch (*Betula*), aspen (*Populus*) and alder (*Alnus*) occupied in Scandinavia and Siberia; all habitat types in primeval Polish forests; in C Europe occurs in all types of not over-dense deciduous, mixed or coniferous forest, from riparian woodland to subalpine forest. In Japan occurs in open boreal mixed or coniferous forest at 100-1000 m, rarely in lowlands. Requires decaying trees and stumps for foraging, and tall timber for nests and roosts. Outside breeding season also in open areas such as forest clear-cuts, even on outskirts of cities. Mostly lowlands to 2000 m: usually below 1200 m but also up to timber-line in European Alps and in Caucasus; to 1700-2000 m in Asia, but to 2400 m in China.

**Food and Feeding.** Mainly ants (*Camponotus*, *Formica*, *Lasius*) and their brood; at least locally, may switch from *Camponotus* in winter to *Lasius* in spring. Wood-boring beetles and bark beetles and their larvae (e.g. Cerambycidae, Elateridae) also taken; also various other arthropods, and occasionally snails. Reported to break into beehives. Fruits and berries eaten only rarely. Mostly solitary, partners keeping in loose contact. Foraging is concentrated at lower levels on tree trunks, mostly below 3 m, and at bases of trees, and on ground. Both live trees and dead ones are visited; climbs straight on tree trunks and larger branches; very rarely perches crosswise. On ground, moves with a few clumsy hops. Chisels deep elongated rectangular holes into trunks to reach food items in burrows deep inside; bark removed by tangential blows, or pried off in large pieces. Drinking from sap wells recorded, also the drilling of wells. Seems to be well aware of location of ant nests in its territory, is able to locate them even under deep snow.

**Breeding.** Laying mid-Mar to mid-May, but sexual activities may begin in mid-Jan; long period of pair-formation, during which final location of nest decided upon. Nest-excavation takes 10-15 days, site in tall tree, in most cases (c. 75%) living one, either coniferous or deciduous, at height of 3-27 m, mostly 5-10 m (mean height of 102 nests in Norway was 8.0 m), entrance a vertical oval, average

dimensions 13 cm × 8.5 cm, cavity depth up to c. 60 cm; often (up to 50% of nestings) old hole reused, or telephone pole used; active nests at least 900 m apart. Clutch 2-6 eggs, usually 3-5, average clutch size ranging from c. 4.8 eggs in Sweden to 3.3 eggs in S Germany, and earlier clutches tend to be larger; incubation by both sexes, only male at night, period 12-14 days; both parents also brood chicks, for c. 8 days, and both feed them, by regurgitation; fledging period 24-31 days, usually 27-28 days; juveniles fed for up to 1 month, generally by male parent. Fledging success averaged 2.7 in Germany, 4.4 in Finland; martens (*Martes*) are major nest predators.

**Movements.** Resident in most areas, and even N populations only partially migratory; juvenile dispersal more pronounced. Scandinavian populations migrate in Sept or earlier, early migrants or dispersing birds recorded in Aug and early Sept in C Europe; some movements also in winter; movements of between 500 km and 1000 km recorded. Vertical winter movements take place in some mountainous regions.

**Status and Conservation.** Not globally threatened. Locally common in some W parts of range, but more uncommon in E. Estimated population of c. 316,000 pairs in European Russia and c. 233,000 pairs in rest of Europe in late 1990's, of which 60,000 in Belarus and 50,000 in Germany. Densities usually low, e.g. 1 pair/300-1000 ha in C Europe. Stable or increasing in W; during 20th century range extended in W Europe and EC European lowlands, and since c. 1970 has colonized large areas where formerly absent. Has also spread recently in Japan, with extension from Hokkaido S to other parts of country. A key species in many forests, as it creates holes for wide variety of other hole-nesters.

**Bibliography.** Alatalo (1978), Arisawa (1991), Aschoff (1967), Beaman & Madge (1998), Blagosklonov (1968), Blume (1956, 1961, 1981, 1996), Borgstrom (1989), Brazil (1991), Burow (1970), Callegari (1955), Christensen (1984, 1995a, 1995b), Christensen & Sorensen (1986), Clarenbach (1998), Cramp (1985), Cuisin (1967, 1967-1968, 1972, 1975, 1976, 1977, 1980, 1981, 1983, 1985, 1988, 1990, 1992, 1997, 1998), Dementiev (1939), Dementiev *et al.* (1966), Díaz (1997), Díaz *et al.* (1996), Diener (1996), Érdár (1962), Échécopar & Hüe (1978), Eygenraam (1947), Fernández & Azkona (1996), Ferry *et al.* (1957), Fitter (1992), Garoche & Sohler (1992), Gatter (1977, 1981), Gentilin (1967), Gorman (1998b), Grebe (1998), Guichard (1961), Haessler (1989), Hagemeijer & Blair (1997), Hågvær & Hågvær (1989), Hågvær *et al.* (1990), Haila & Jarvinen (1977), Hansen (1984, 1987, 1989), Haribal & Ganguli-Lachungpa (1991), Hasse (1961), Heath *et al.* (2000), Hüe & Échécopar (1970), Ishigaki *et al.* (1987), Iso & Fujimaki (1990), Ivanchev (1995), Järvinen *et al.* (1977), Johansen (1989a, 1989b), Johnsson (1993), Johnsson *et al.* (1993), Kojima & Arikawa (1983), Kojima & Matsuoka (1985), Kuhlke (1985), Labidoire (1992), Lang & Rost (1990a, 1990b), Lange (1995, 1996), Liu Huanjin & Shen Shouyi (1988), Lucker (1992), MacKinnon & Phillips (2000), Majewski & Rolstad (1993), Matsumoto (1987), Matsuoka & Kojima (1979a), Mauersberger *et al.* (1982), Mayaud (1950), Melde (1994), Merikallio (1958), Mikusinski (1995, 1997, 2001), Mikusinski & Angelstam (1997, 1998), Mosansky (1986), Mouillard (1946), Mueller (1998), Mulhauser, Kaiser & Claude (2000), Mulhauser, Kaiser & Junod (2001), Müller (1977), Nilsson, Johnsson & Tjernberg (1991, 1993a, 1993b), Nilsson, Olsson *et al.* (1992), Ogasawara & Izumi (1977, 1978), de Pardieu (1937), Pavlík (1994), Pechacek (1992, 1995, 1996), Pechacek & Křiřtin (1993), Prodon (1991), Purroy (1997), Radermacher (1970), Ravussin & Sernet (1975), Rivière (1990), Rogacheva (1992), Rolstad & Rolstad (2000), Rolstad, Majewski & Rolstad (1998), Rolstad, Rolstad & Saeteren (2000), Rost *et al.* (1992), Roze (1987), Rudat *et al.* (1979), Ruge & Bretzendorfer (1981), Sautereau & Courtillot (1961), Short (1985b), Snow & Perrins (1998), Sollien *et al.* (1977), Striegler *et al.* (1982), Svensson *et al.* (1999), Tjernberg *et al.* (1993), Tobalske & Tobalske (1999), Villarán (1999), Voous (1961), Wesolowski & Tomialojc (1986), Zhao Zhengjie (1995).

PLATE 44

inches 7  
cm 18

Genus *CAMPEPHILUS* G. R. Gray, 1840

172. Powerful Woodpecker

*Campephilus pollens*

French: Pic puissant      German: Zimtbindenspecht      Spanish: Picamaderos Poderoso

**Taxonomy.** *Picus pollens* Bonaparte, 1845, Colombia. Formerly placed in genus *Phloeoeastes* with seven other species, all of which are now lumped into *Campephilus*. Two subspecies recognized.  
**Subspecies and Distribution.**  
*C. p. pollens* (Bonaparte, 1845) - Andes from NC Colombia and SW Venezuela (Táchira) S to Ecuador.  
*C. p. peruvianus* (Cory, 1915) - Peru (S to Pasco).

**Descriptive notes.** c. 32 cm. Male has bright red forehead to crest, sometimes some black and white of feather bases visible, white band from lores to lower rear edge of ear-coverts continuing down side of neck to side of upper breast; rest of head, including chin and throat, black; black hindneck, mantle, scapulars and upper back, narrow white stripes on sides of mantle (often some cinnamon markings) more or less meeting at top of lower back and often joining with neck stripes; white lower back and rump, edges with a few dark-barred cinnamon-buff feathers, black uppertail-coverts; uperwing black, primaries narrowly tipped

white, white spots or bars on inner webs of secondaries and all but outermost primaries; uppertail black, very occasionally white spots towards tips of outer feathers, only 10 feathers (not 12); black central breast, cinnamon-buff lower breast to undertail-coverts with black bars or chevrons, latter less pronounced on belly; underwing blackish, barred white, coverts white; long bill chisel-tipped, culmen slightly curved, broad across nostrils, black; iris white to pinkish-white; legs dark grey. Female has red areas of head replaced with black. Juvenile duller and browner than adult, more barring on back, duller and greyer with broader barring below, crest feathers longer, head pattern as respective adult. Race *peruvianus* differs from nominate in having lower back and rump cinnamon-buff and often strongly barred, often narrow cinnamon-buff bars on uppertail-coverts. Voice. Commonest call nasal "kyaaah" or "peeyáw", often repeated; fast "kikikikikawh", mostly in flight; descending "kikikiki-keh-keh-kah-kah" in excitement. Loud instrumental signal a brief double rap.

**Habitat.** Inhabits mature montane forest, humid and wet forest, cloudforest, and forest borders; also occurs in secondary forest, and open forest. Recorded between 900 m and 3750 m, mainly at 1700-2600 m.

**Food and Feeding.** Details of diet not documented. Often in pairs. Forages in interior of forest, at all levels, predominantly on trunks and large limbs.

**Breeding.** Season apparently Apr-Aug. Nest situated in tree or telegraph pole, high up, e.g. at 7 m. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Local in Colombia; rare to uncommon and local in Ecuador; rare in Peru. Occurs in Cueva de los Guácharos National Park and La Planada Nature Reserve (Colombia) and also in Podocarpus National Park (Ecuador). Not often seen; appears to require very large home range.

**Bibliography.** Allen (1998), Bloch *et al.* (1991), Butler (1979), Clements & Shany (2001), Davies *et al.* (1994), Donegan & Dávalos (1999), Fjeldsá & Krabbe (1990), Hilty (1985), Hilty & Brown (1986), Hornbuckle (1999), Kirwan & Marlow (1996), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Poulsen (1996), Ridgely & Greenfield (2001), Ridgely *et al.* (1998), Salaman (1994), Salaman *et al.* (1999), Stotz *et al.* (1996), Vélez & Velázquez (1998), Williams & Tobias (1994).

173. Crimson-bellied Woodpecker

*Campephilus haematogaster*

French: Pic superbe      German: Blutbauchspecht      Spanish: Picamaderos Ventrirrojo  
Other common names: Splendid Woodpecker (*splendens*)

**Taxonomy.** *Picus haematogaster* Tschudi, 1844, Peru. Formerly placed in genus *Phloeoeastes* with seven other species, all of which are now lumped into *Campephilus*. Race *splendens*, sometimes regarded as a separate species, appears to differ vocally; further study needed. Two subspecies currently recognized.

**Subspecies and Distribution.**

*C. h. splendens* Hargitt, 1889 - Panama to W Ecuador.  
*C. h. haematogaster* (Tschudi, 1844) - E Colombia to E Peru.

**Descriptive notes.** 33-34 cm; 225-250 g. Male has buffish nasal tufts, thin buff supercilium behind eye, broad buff cheekband, black line from upper bill to mid crown side, black upper ear-coverts, black chin to foreneck; rest of head red, hindneck and entire underparts red; mantle, scapulars and upper back black to brownish-black, lower back and rump deep red, uppertail-coverts black; upperwing black or brownish-black, primaries narrowly tipped pale when fresh, large white to buff-white spots on inner webs of secondaries and all but outermost primaries; uppertail black; underwing blackish, barred pale, coverts white; in worn plumage, red areas duller, black feather bases visible on crown and below, black areas of plumage browner; long bill almost straight, chisel-tipped, broad across nostrils, grey-black to black; iris red-brown, orbital skin black; legs brownish-black. Female differs from male in having buffish-white cheekband con-

tinuing broadly down neck side to upper breast side. Juvenile duller than adult, black areas browner, less red below, has forehead more sooty-coloured, sexes differ as for adults. Race *splendens* has larger black feather bases than nominate, especially on head, red tips on throat and foreneck, back narrowly barred, feathers of underparts black-based with barred central part. Voice. Call a loud "stk! st-kr-r-r-r-r-r-r", c. 2 seconds long, drumroll fast series of 3-4 loud raps; race *splendens* a loud "stk!", drum a strong double rap like that of *C. rubricollis*.

**Habitat.** Humid and wet forest, montane forest, and edges; most often inside tall forest, such as semi-open *várzea* forest. From lowlands to 1600 m in Panama; 800-1700 m in Ecuador; 900-2200 m in Peru.

**Food and Feeding.** Large adult beetles, and very large larvae of wood-boring beetles. Often in pairs. Forages at low levels, usually close to ground, in dense forest, especially on trunks of big trees; visits slightly higher levels in more open habitats. Hammers, probes in crevices. Where sympatric with *C. gayaquilensis*, separated ecologically by preference for lower levels.

**Breeding.** Mar-May in Panama, and Sept-Apr in Colombia and Ecuador. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally rather rare in Panama, though perhaps somewhat more numerous in E; locally quite numerous in Colombia; rare to locally uncommon in Ecuador; rare in Peru. Occurs in El Pangán Reserve (Colombia), and in Machu Picchu Historical Sanctuary (Peru). Recorded at El Placer (Ecuador), and at Tingo María and Abra Patricia (Peru).

**Bibliography.** Anon. (1998b), Balchin & Toyne (1998), Butler (1979), Clements & Shany (2001), Davies *et al.* (1994), Hilty (1997), Hilty & Brown (1986), Hornbuckle (1999), Meyer de Schauensee (1982), Olrog (1968), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely *et al.* (1998), Robbins *et al.* (1985), Salaman (1994), Stotz *et al.* (1996), Walker (2001), Wetmore (1968a), Williams & Tobias (1994).

174. Red-necked Woodpecker

*Campephilus rubricollis*

French: Pic à cou rouge      German: Rothalspecht      Spanish: Picamaderos Cuellirrojo

**Taxonomy.** *Picus rubricollis* Boddaert, 1783, Cayenne. Formerly placed in genus *Phloeoeastes* with seven other species, all of which are now lumped into *Campephilus*. Race *trachelopyrus* intergrades with nominate in SW of range. Three subspecies recognized.

**Subspecies and Distribution.**

*C. r. rubricollis* (Boddaert, 1783) - E Colombia and E Ecuador to Venezuela, the Guianas and N Brazil (N of Amazon).  
*C. r. trachelopyrus* (Malherbe, 1857) - NE Peru and W Brazil (S of Amazon) S to WC Bolivia (La Paz).  
*C. r. olallae* (Gyldenstolpe, 1945) - Brazil S of Amazon, from R Madeira E to Pará and Maranhão, and S to C Bolivia (Cochabamba) and N Mato Grosso.

**Descriptive notes.** 30-32 cm; 178-239 g. Male has small oval spot of black and white on lower rear ear-coverts; rest of head, crest and neck to uppermost mantle bright red, feathers of neck and side of head black-based and with cinnamon bar below red tip (some barring usually visible when worn); upperparts black to brownish-black, uperwing black, bases of primaries with extensive rufous on inner webs and shafts, primaries very occasionally (fresh plumage) with very small pale rufous to whitish tips; uppertail black; rufous to rufous-cinnamon below, feathers of upper and occasionally lower breast with red tips; underwing

rufous, coverts darker, blackish tip and trailing edge; long bill almost straight, chisel-tipped, broad across nostrils, pale ivory to greyish or pale yellow; iris yellowish-white; legs blackish-grey or olive. Female lacks ear-covert spot, instead has black-bordered broad whitish malar stripe from base of bill to lower ear-coverts. Juvenile duller than adult, more brownish-black and orange-red, male with whitish malar, usually some red tips, some black feathering on foreneck, female like adult but with black extending to forehead. Race *trachelopyrus* is larger than nominate, darker, more chestnut, below, with red tips extending to lower breast or to belly, rufous in wing on both webs; *olallae* is slightly smaller than previous, and brighter. Voice. Explosive nasal "ngkah-ngkah", "kiahh", and "querra-querra", similar to calls of *C. melanoleucos*. Drumming a loud double rap, "tô-ro".

**Habitat.** Rainforest, *terra firme* and *várzea* forests, cloudforest, forest edge, light second growth, semi-open woodland on sand, and riverine woodland in savanna regions. Mainly lowlands, usually to 600 m, locally (S Venezuela, NW Brazil) to 1800 m, even 2400 m (La Paz, Bolivia).

**Food and Feeding.** Large larvae of beetles and moths (Pyralidae). In pairs or small family parties. Forages actively from middle to upper levels, on trunks and limbs of tall trees; often visits lower storey and canopy.

**Breeding.** Jan-May in N part of range, Nov in Ecuador, and Sept in Peru. Nest situated in live or dead trunk; has oval-shaped entrance; only one chick recorded at any particular nest. No other information available.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Often the commonest large woodpecker within its range. Rare to uncommon and seemingly local in Ecuador; fairly common in Peru. Occurs in several protected areas, e.g. Canaima National Park, and Imataca Forest Reserve and El Dorado (Venezuela), Amacayacu National Park (Colombia), Cuyabeno Reserve (Ecuador), Tambopata Re-

serve (Peru) and Rio Cristalino Private Reserve (Brazil). Research required to investigate its breeding behaviour.

**Bibliography.** Allen (1995), Brace *et al.* (1997), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Donahue (1994), Duhs (1992), Fjeldså & Krabbe (1990), Flores *et al.* (2001), González (1998), Haverschmidt & Mees (1994), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Oren & Parker (1997), Peres & Whittaker (1991), Perry *et al.* (1997), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Robinson & Terborgh (1997), Short (1985b), Sick (1993), da Silva (1996), Snyder (1966), Stager (1961a), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Thiollay & Jullien (1998), Tostain *et al.* (1992), Traylor (1958), Willard *et al.* (1991).

## 175. Robust Woodpecker

### *Campephilus robustus*

**French:** Pic robuste      **German:** Scharlachkopfspecht      **Spanish:** Picamaderos Robusto

**Taxonomy.** *Picus robustus* M. H. K. Lichtenstein, 1819, Brazil.

Formerly placed in genus *Phloeocastus* with seven other species, all of which are now lumped into *Campephilus*. Size of present species increases slightly from N to S, but insufficient to warrant separation of any geographical races. Monotypic.

**Distribution.** E Brazil (S from S Bahia and E Goiás) S to E Paraguay, NE Argentina (Misiones, Corrientes) and Rio Grande do Sul.

**Descriptive notes.** 32–37 cm; 230–294 g. Large, distinctive woodpecker. Male has small oval black and white spot on lower rear ear-coverts; rest of head, small crest, and neck to uppermost breast bright red, often some black and buff of feather bases visible, especially on neck and side of head (more obvious when plumage worn); whitish upperparts tinged pale buff or cinnamon, a few blackish bars on upper mantle and often at sides; black upperwing, coverts and scapulars, small rusty-buff spots on inner webs of flight-feathers; uppertail black; underparts from breast buff to whitish-buff, barred black, bars narrower or occasionally absent on belly; underwing blackish-brown, rufous-buff coverts and spots on flight-feathers; long bill almost straight, chisel-tipped, broad across nostrils, horn-coloured; iris white to yellow-white; legs dark grey. Female lacks ear-covert spot, has black-margined whitish malar stripe, blackish chin. Juvenile duller than adult, browner, with less contrasting barring below, undertail-coverts usually unbarred, upperparts generally whiter, head pattern as adult female, male with red tips in malar area. VOICE. Call “kee” or “kew”, both when perched and in flight; also “psó-ko po-po-po-por” series. Drumming a double tap, “to-plóp” or “thump-ump”, 1–3 per minute.

**Habitat.** Humid forest, araucaria forest; occurs in disturbed forest only if large trees present. Lowlands to 1000 m, in hills to 2200 m.

**Food and Feeding.** Beetles, apparently also wood-boring larvae; berries sometimes taken. Singly, or in pairs or family parties; rarely joins mixed-species flocks. Forages at all levels, with slight preference for middle storey; only rarely on ground. Prefers larger trees, dead or living; visits mainly trunks and base of branches. Pecks and hammers vigorously; hammering may, rarely, create large excavations. Also probes, and removes bark.

**Breeding.** Two records, from Oct and Jan, of birds excavating holes 3.5–4.5 m up dead trees in forest clearings. Only known display is wing-spreading. No further information available.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Not uncommon in S of range. Occurs in Caaguazú National Park and Estancia San Antonio Private Nature Reserve (Paraguay), and in neighbouring Iguazú and Iguazú National Parks (Brazil/Argentina). Has possibly extended range in SE Brazil, where recent sightings in Rio Grande do Sul much farther S than previous records. Poorly known; requires research on its ecology and breeding.

**Bibliography.** Aleixo & Galetti (1997), dos Anjos & Schuchmann (1997), dos Anjos *et al.* (1997), Belton (1984), Brooks *et al.* (1993), Buzzetti (2000), Cándido (2000), Canevari *et al.* (1991), Descourtiz (1983), Duhs (1992), Hayes (1995), Hayes & Scharf (1995a, 1995b), Lowen *et al.* (1995), Madroño, Clay, Robbins *et al.* (1997), Madroño, Robbins & Zyskowski (1997), Maurício & Dias (1998), Meyer de Schauensee (1982), Olrog (1968), Parker & Goerck (1997), de la Peña (1994), Pereyra (1950), Pichorim *et al.* (2000), do Rosário (1996), Saibene *et al.* (1996), Sargeant & Wall (1996), Sick (1993), da Silva (1996), Silveira (1998), Stotz *et al.* (1996), Tobias *et al.* (1993), Urben-Filho *et al.* (2000), Willis (1989).

## 176. Pale-billed Woodpecker

### *Campephilus guatemalensis*

**French:** Pic à bec clair      **German:** Königspecht      **Spanish:** Picamaderos Piquiclaro  
**Other common names:** Flint-billed Woodpecker

**Taxonomy.** *Picus guatemalensis* Hartlaub, 1844, Guatemala.

Formerly placed in genus *Phloeocastus* with seven other species, all of which are now lumped into *Campephilus*. Forms a superspecies with *C. melanoleucos* and *C. gayaquilensis*. Birds from Sonora described as race *dorsofasciatus*, on basis of more barred rump, but this character matched by individuals of *nelsoni*. Three subspecies recognized.

**Subspecies and Distribution.**

*C. g. nelsoni* (Ridgway, 1911) - W Mexico, from S Sonora S to Oaxaca.

*C. g. regius* Reichenbach, 1854 - E Mexico, from Tamaulipas S to Veracruz.

*C. g. guatemalensis* (Hartlaub, 1844) - Veracruz to W Panama.

**Descriptive notes.** 31–38 cm; 205–244 g (*guatemalensis*), 263–282 g (*regius*). Male has entire head and short bushy crest red, usually slightly darker on rear ear-coverts, often some black and white of feather bases showing through when worn; black neck, upper breast and upperparts, white stripe on neck side continuing along side of mantle to centre of back, occasionally some paler bars on lower back, rump and uppertail-coverts; upperwing black to brownish-black, whitish bases to flight-feathers, in fresh plumage white tips to primaries; uppertail black; underparts below breast buffish-white, flanks and belly tinged pale greenish, all barred blackish-brown; underwing whitish or pale yellowish, blacker tip and trailing edge; undertail brown to yellow-brown, paler at base; long bill straight, chisel-tipped, broad across nostrils, ivory-coloured, base tinged blue-grey; iris pale yellow, orbital skin greyish; legs greenish-grey to grey-brown. Female differs from male in having black forehead, crown and centre of crest, black chin and throat. Juvenile duller and browner above than adult,

browner with more obscure barring below, with bill dark, eyes grey to brown, head pattern as female but more orange, head side more dark reddish-brown, male soon like adult. Race *nelsoni* is on average slightly smaller than nominate, browner above, less buff-tinged below, with greater tendency towards barring on rump, especially in N of range; *regius* is larger and longer-billed than nominate. VOICE. Loud bleating “kint”, similar to that of *C. principalis*; loud nasal rattle, “ka ka ka ka ka kay, nyuck, nyuck”; whining or moaning sounds, or low “keeu keeu keeu keeu”, in intimate contacts. Instrumental signal of 2 powerful taps in quick succession, second stroke not so loud; roll of c. 7 strokes also reported.

**Habitat.** Humid and dry forest and edge, clearings with scattered trees, also tall second growth, plantations and mangroves. In lower parts of pine-oak (*Pinus-Quercus*) woodland in N parts of range. Tall rainforest occupied in areas where *Dryocopus lineatus* is absent. Although basically a forest bird, it often forages in cleared areas. Lowlands and foothills to 2000 m in Mexico and Guatemala; to 1000 m in N Costa Rica, and to 1200 m and locally 1500 m on S Pacific slope of Costa Rica and in Panama.

**Food and Feeding.** Insects, mostly larvae of wood-boring beetles (frequently Cerambycidae), scarabaeid larvae and ant larvae, comprise more than 70% of diet; some fruit also taken. Singly or in pairs. Forages at all heights, but middle to fairly high levels preferred; comes lower at edges, clearings, or in second growth. Trunks and larger branches favoured, but small twigs also investigated. Digs deeply into decaying trunks with hammering and pecking, removes large flakes and splinters, also probes into such excavations; removes bark from dead wood; other feeding techniques uncommon.

**Breeding.** Jan–May in Mexico and N Central America, and Aug–Dec farther S. Paired throughout year. Crest-raising display. Nest a deep cavity, excavated by both sexes, 4–15 m up in large trunk. Clutch 2 eggs; incubation by both sexes, in long bouts, period not documented; both also feed chicks, directly rather than by regurgitation; fledging period not recorded.

**Movements.** Resident; possibly some local movements.

**Status and Conservation.** Not globally threatened. Fairly common to common; widespread in suitable habitats. Locally common in wholly or partly forested areas, notably in Costa Rica, where present in Corcovado, Santa Rosa, Manuel Antonio, Cahuita, Barra Honda and Braulio Carrillo National Parks, Carara Biological Reserve, Guayabo National Monument, and Finca La Selva; also present in Tikal National Park (Guatemala). Seems to be fairly adaptable; accepts more open forest.

**Bibliography.** Anon. ## 177. Crimson-crested Woodpecker

### *Campephilus melanoleucos*

**French:** Pic de Malherbe      **German:** Schwarzkehlspecht      **Spanish:** Picamaderos Barbinegro  
**Other common names:** Black-and-white Woodpecker; Malherbe’s Woodpecker (*malherbii*)

**Taxonomy.** *Picus melanoleucos* J. F. Gmelin, 1788, Surinam.

Formerly placed in genus *Phloeocastus* with seven other species, all of which are now lumped into *Campephilus*. Forms a superspecies with *C. guatemalensis* and *C. gayaquilensis*. Possibly conspecific with latter. Races intergrade quite extensively; birds from S half of range formerly grouped together as race *albistrois*. Three subspecies recognized.

**Subspecies and Distribution.**

*C. m. malherbii* G. R. Gray, 1845 - W Panama E to N & C Colombia.

*C. m. melanoleucos* (J. F. Gmelin, 1788) - E of Andes, from Colombia E to Trinidad and NE Brazil, S to Bolivia, Paraguay, N & NE Argentina and Mato Grosso.

*C. m. cearae* (Cory, 1915) - E & S Brazil.

**Descriptive notes.** 33–38 cm; 181–284 g. Large woodpecker. Male has cream-buff feathering around base of bill, narrow black line across lower forehead, small oval area of black and white at lower rear ear-coverts; rest of head and crest red, throat black; neck to upper breast and upperparts black, white stripe down neck and side of mantle to centre of back, often with a few black spots or bars on back; upperwing black, primaries with small white tips when fresh, small area of white at bases of inner webs; uppertail black; lower breast to undertail-coverts pale buffish-white, sometimes tinged green, barred blackish-brown; underwing

white, blackish tip and trailing edge; long bill chisel-tipped, culmen slightly curved, broad across nostrils, greyish-ivory to whitish, darker base; iris white to pale yellowish, orbital skin greyish; legs grey or green-grey. Female has slightly longer crest than male, also black central forehead and crown to centre of crest, broad whitish malar area with black borders. Juvenile browner above than adult, usually somewhat darker with heavier barring below, both sexes with pinkish-red head patterned like adult female’s but broader black area across lower ear-coverts, whitish supercilium, male soon acquiring more red. Race *malherbii* has dark grey to brown-grey bill, darker, more cinnamon-buff, ground colour below, both sexes with more extensive red around eyes; *cearae* is noticeably smaller, with shorter wing, proportionately shorter tail. VOICE. Main call likened to tree-frog’s, “kwirr kwirr-ah” or “squeer squeer-ah-hah” or “kiahrrh rai-ai-ai-ai”, when perched or on landing, as contact; “ca” and “ca-wa-r-r” in moderate agitation; shrill piping “put put puttas”, sometimes continued for minutes, during intense excitement; “chiz-ik” in display; low intimate notes as “wuk wuk”, “wrr wrr”, “wun wun” and “uh uh”, before copulation and at change-over at nest. Both sexes drum, male more, especially during nesting season, strong blow followed by 2–4 weak strokes, “da-drrrr”, usually 1–2 rolls per minute, rarely 3; single “torrrrr” roll given throughout day, presumably by partners as contact when moving through forest.

**Habitat.** Very wide range of habitats: cloudforest, rainforest, *terra firme* and *várzea* forest, gallery forest and deciduous forest, also rather open woodland in savanna. Occurs in second growth, clearings, forest edge, semi-open country, plantations, palm groves, pastures, and swampy areas; sometimes at single trees well away from forest. Presence of big dead trees probably important element in habitat. Occurs in lowlands, up to 900 m in Panama; in Venezuela, up to 2000 m in N and to 950 m in S; up to 1350 m, but mostly around 900 m, in Ecuador; up to 1500 m in Peru; up to 2500 m, locally 3100 m, elsewhere in Andes.

**Food and Feeding.** Chiefly larvae of large (e.g. 4 cm) wood-boring beetles, also hard-shelled insects, ants, termites (Isoptera); takes pyralid caterpillars, also smaller insects, and berries (Loranthaceae). In pairs or small groups; pair-members usually within 15 m of each other, often much closer. Forages at heights varying from 6 m to 25 m, mostly at intermediate levels, on tall, dead tree trunks in forest, or on isolated trees a considerable distance from forest or woodland. Moves from one tree to the next, rather than making long flights from one profitable tree to another; explores many parts of tree in quick succession. Moves along underside of dead limbs high up in crown; frequently hangs upside-down on relatively thin branches. Versatile feeder, with strong preference for wood-boring techniques. Uncovers prey with few powerful blows against bark or surface layers of wood; light taps probably more exploratory. Excavates on well-rotted stubs, cavities 10 cm or more in depth created; combines pecking with sideways blows to dislodge pieces of loose bark; also probes natural cavities or clumps of epiphytes.

**Breeding.** Mainly Nov-Jan in Panama, from end of rainy season to beginning of dry; Dec-May in Colombia, Apr-Jul in N Venezuela, Dec-Mar in the Guianas; Jul in N & NW Brazil, May-Dec elsewhere; mostly May-Oct in S, and Sept-Nov in Argentina. Displays with crest-raising, head-swinging, simultaneous calling. Nest-hole excavated by both sexes, high up in stub, preferably of large diameter (45-50 cm), entrance hole oval in shape; aragaris (*Pteroglossus*) important hole competitors; territory relatively small. Clutch 2-3 eggs, occasionally 4; both sexes incubate, stints lasting over 30 minutes, period not recorded; both also brood and feed chicks, nestling period not documented; young remain with parents almost until following breeding season.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common in much of range; uncommon in some regions, e.g. Trinidad. Occurs in numerous protected areas throughout extensive range, e.g. Henri Pittier, Ciénaga de Catatumbo, Canaima and Morrocoy National Parks (Venezuela), Cuyabeno Reserve (Ecuador), Manu National Park and Alpuhuayo-Mishana Reserve (Peru) and Rio Cristalino Private Reserve (Brazil). Acceptance of more open habitats suggests that it is unlikely to become threatened in immediate future.

**Bibliography.** dos Anjos & Schuchmann (1997), Brace *et al.* (1997), Canaday & Jost (1999), Canevari *et al.* (1991), Capper, Clay, Madroño & Mazar Barnett (2001), Chebez (1994), Clements & Shany (2001), ffrench (1991), Figueiredo & Lo (2000), Fjeldså & Krabbe (1990), Haverschmidt & Mees (1994), Hayes (1995), Herklotz (1961), Hilty (1997), Hilty & Brown (1986), Kilham (1972a, 1983), Marini (2001), Meyer de Schauensee & Phelps (1978), Oren & Parker (1997), de la Peña (1994), Pinto & Camargo (1961), Piratelli *et al.* (2000), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Robbins *et al.* (1985), Robinson (1997), Robinson & Terborgh (1997), Short (1975, 1985b), Sick (1993), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Tostain *et al.* (1992), Wetmore (1939, 1968a), Willis (1980).

## 178. Guayaquil Woodpecker *Campephilus gayaquilensis*

**French:** Pic de Guayaquil    **German:** Guayaquilspecht    **Spanish:** Picamaderos de Guayaquil

**Taxonomy.** *Picus Gayaquilensis* Lesson, 1845, Guayaquil, Ecuador.

Formerly placed in genus *Phloeocastus* with seven other species, all of which are now lumped into *Campephilus*. Forms a superspecies with *C. guatemalensis* and *C. melanoleucos*. May be conspecific with latter. Monotypic.

**Distribution.** W slope of Andes and adjacent lowlands, from SW Colombia (SW Cauca) S to NW Peru (S to Cajamarca).

**Descriptive notes.** 32-34 cm; 230-253 g. Large woodpecker. Male has small black and white oval spot on rear lower ear-coverts; rest of head and crest red, sometimes black and buff of feather bases showing through; black chin and throat sometimes with red feather tips at side; neck to upper breast, mantle, scapulars and upper back black, white stripe down side of neck and mantle to centre of back; lower back to uppertail-coverts variably barred pale whitish-buff and blackish, central part of back and rump sometimes all blackish; upperwing brownish-black to black, flight-feathers browner with small cinnamon or buff patch on inner webs; uppertail dark brown to black-brown; whitish-buff to pale cinnamon-buff lower breast to undertail-coverts barred brownish-black, bars narrower on lower underparts; underwing white, pale cinnamon at bases of primaries, brown tip and trailing edge; long bill chisel-tipped, culmen slightly curved, broad across nostrils, greyish, paler lower mandible; iris pale yellow; legs grey-brown to greenish-grey. Differs from *C. melanoleucos* mainly in lacking pale area around bill base. Female has broad creamy malar stripe joining with white neck stripe, black patch at lower rear ear-coverts, fully black chin and throat. Juvenile as adult but normally less barred rump and underparts, male head pattern much as adult female but some red tips in white malar, female with black band through crown centre and dark cheekband back to hindneck, patch of white on rear side of head. **VOICE.** Rather similar to *C. melanoleucos*. Commonest call is a liquid, rolling "kwi-kwi-kwe-rrrrrr", often given upon alighting on a tree trunk; when excited, "kwik-kwik-kwikerrrr" and "kik-kwididd" notes, and variations on this theme for long periods. Drumming a loud, far-carrying double rap.

**Habitat.** Humid to dry deciduous forest, forest edge, and tall second growth. Recorded up to 800 m, occasionally up to 1500 m in Ecuador and Peru. Replaces *C. melanoleucos* to W of Andes.

**Food and Feeding.** Details of diet not documented; probably similar to *C. melanoleucos*. Often in pairs. Forages on dead branches in canopy and in emergent trees; easily detected by its loud hammering. Where sympatric with *C. haematogaster*, separated ecologically by preference for lower levels.

**Breeding.** Season Oct and May. No details known.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Uncommon to locally fairly common in Ecuador; uncommon in Peru. In Ecuador, occurs in Rio Palenque Science Centre, Tinlandia Natural Reserve and Cerro Blanco Protected Forest; substantial population in Machalilla National Park. In Peru, recorded in Tumbes National Reserve and Cerros de Amotape National Park. Occurs naturally at low densities. The dry deciduous and humid forests

inhabited by this woodpecker have suffered extensive clearance; remaining forest extremely fragmented, with very few and very small patches, but appears to survive well in disturbed patchy forest. Further habitat loss, however, could easily lead to its becoming threatened.

**Bibliography.** Allen (1998), Becker & López (1997), Best & Clarke (1991), Bloch *et al.* (1991), Butler (1979), Clements & Shany (2001), Hilty & Brown (1986), Kirwan & Marlow (1996), Meyer de Schauensee (1982), Olrog (1968), Parker *et al.* (1982), Pople *et al.* (1997), Ridgely & Greenfield (2001), Ridgely *et al.* (1998), Rodner *et al.* (2000), Salaman (1994), Short (1985b), Stattersfield & Capper (2000), Stotz *et al.* (1996), Williams, M.D. (1980), Williams, R.S.R. & Tobias (1994).

## 179. Cream-backed Woodpecker *Campephilus leucopogon*

**French:** Pic à dos crème    **German:** Weißmantelspecht    **Spanish:** Picamaderos Dorsiblanco

**Taxonomy.** *Picus leucopogon* Valenciennes, 1826, Brazil.

Formerly placed in genus *Phloeocastus* with seven other species, all of which are now lumped into *Campephilus*. Monotypic.

**Distribution.** NC Bolivia (Cochabamba, Santa Cruz) and W & C Paraguay to NC Argentina (S to La Rioja, Córdoba, Entre Ríos, Corrientes), N Uruguay and SE Brazil (W Rio Grande do Sul).

**Descriptive notes.** 28-30 cm; 203-281 g. Rather large, with short tail. Male has small oval spot of black and white at lower rear ear-coverts; rest of head and crest red, red tips extending variable distance down foreneck (latter all black when worn); whitish mantle feathers tipped pale cinnamon-buff, lower back to uppertail-coverts black, sometimes a few black-barred buff feathers in centre of back; upperwing black, flight-feathers with large area of pale cinnamon towards bases of inner webs; uppertail black; entirely black below; underwing black, pale cinnamon at bases of flight-feathers, narrow whitish to pale cinnamon-buff

on leading coverts; long bill straight, chisel-tipped, very broad across nostrils, ivory-coloured; iris pale yellow; legs grey. Female has longer crest than male, also black from forehead through crown to central part of crest, black around eyes and along lower ear-coverts, creamy cheekband bordered by black, black upper chin, all-black neck. Juvenile has red of head more orange and less extensive, male similar to adult female but red on crown to crest, red feathers in white cheekband, more black on chin, female with red restricted to rear crown side and underside of crest. **VOICE.** Call "pi-ow" or "kwee-yaw", sometimes repeated; whirring notes during close encounters between partners. Drums a double rap.

**Habitat.** Xeric woodlands of Chaco; occurs in savanna, pastures with copses, groves, woodland and transitional forest, at up to 2500 m.

**Food and Feeding.** Larvae of beetles. Generally solitary outside breeding season. Forages in tall trees, isolated trees in open areas; descends to fallen logs. Forages mainly by powerful hammering; pecking and probing less frequent.

**Breeding.** Mainly in Sept, also Oct-Nov. Nest-hole built at 6-8 m in tree or palm; entrance described as "droplet-shaped". No data on clutch size and incubation and fledging periods; both adults feed nestlings.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Poorly known; probably not common. Occurs in El Rey and Calilegua National Parks and Chancani Provincial Park (Argentina).

**Bibliography.** Belton (1984), Brooks, D.M. (1997), Brooks, T.M. *et al.* (1993), Canevari *et al.* (1991), Contreras (1983), Contreras *et al.* (1990), Dubs (1983, 1992), Fjeldså & Mayer (1996), Hayes (1995), Krabbe *et al.* (1996), López (1997), López de Casenave *et al.* (1998), Mazar Barnett & Pearman (2001), Meyer de Schauensee (1982), Miserendino (1998), Nellar (1993), Norez *et al.* (1983), Olrog (1968), de la Peña (1994, 1997), Remsen & Traylor (1989), Remsen *et al.* (1986), Schmitt *et al.* (1997), Short (1975), Sick (1993), Stotz *et al.* (1996), Stradi & Hudon (1998), Stradi *et al.* (1998), Tubelis & Tomás (1999), Wetmore (1926).

## 180. Magellanic Woodpecker *Campephilus magellanicus*

**French:** Pic de Magellan    **German:** Magellanspecht    **Spanish:** Picamaderos de Magallanes

**Taxonomy.** *Picus Magellanicus* P. P. King, 1828, Straits of Magellan.

Monotypic.

**Distribution.** Andes of S Chile, from Curico to SW Isla Grande (Tierra del Fuego), and in forested parts of adjacent SW Argentina.

**Descriptive notes.** 36-38 cm; male 312-363 g, female 276-312 g. Large, distinctive woodpecker. Male has entire head and long crest red, normally some black and white bars of feather bases visible (particularly on ear-coverts, crown and throat); rest of plumage glossy black to brown-black, browner on underparts; white on bases of inner webs of primaries, more broadly on inner webs of tertiaries, primaries also with small white tips, usually narrow area of white in alula region; uppertail-coverts, exceptionally also rump, with white shaft streaks, white extending rarely to webs; in worn plumage duller and less glossy, with black and white

bases of head feathers more obvious, white-based feathers of flanks and belly often show, white primary tips lost; long bill chisel-tipped, culmen slightly curved, broad across nostrils, blue-grey to blackish-grey; iris yellow, more golden outer ring, orbital ring grey; legs dark grey. Female is somewhat smaller and shorter-billed than male, has narrow crest longer than male's, black head with red restricted to area around bill. Juvenile much as female but browner, without gloss, smaller crest, male with scattered pale red tips on head. **VOICE.** Most common calls explosive, nasal, of 2 notes, "pi-caá" to "keé-yew"; also more gargling "weerr-weeerrr"; also 1-3 "toot" notes, not so nasal as calls of *C. imperialis* and *C. principalis*; also a loud long "cray-cra-cra-cra-cra-cra". Instrumental signal loud single or double blows.

**Habitat.** Mature *Nothofagus* forest and *Nothofagus-Cupressus* forest, often with bamboo undergrowth; visits disturbed forest and more open woodland. Sea-level to timber-line, at about 2000 m. **Food and Feeding.** Grubs and adult beetles. Singly, in pairs, or in groups of 3-4. Forages at all heights, from ground, on fallen logs, to main trunks and the outer twigs of crown. Both dead and live trees, or parts of trees, are visited. Moves swiftly within a tree, and will cling almost in manner of a tit (Paridae); moves frequently from one tree to another. Pecks and probes; sustained powerful hammering less common. Bark sometimes removed, and deep excavations also created. Possible strong ecological dimorphism; further study needed.

**Breeding.** Oct-Jan. Crest-raising a common display. Nest-hole excavated at 5-15 m above ground, in large tree with dead parts, entrance hole circular to drop-shaped; inter-nest distance c. 2 km. Clutch 1-4 eggs; no information on incubation and fledging periods.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Not uncommon; perhaps locally common; probably decreasing. Occurs in several protected areas, e.g. Nahuelbuta, Vicente Pérez Rosales, Torres del Paine and Puyehué National Parks (Chile); fairly common in Tierra del Fuego National Park (Argentina). Only potentially competing picid within its range is the much smaller and less numerous *Picooides lignarius*. Temperate forest in N of range in Chile was recently destroyed by fire, causing significant loss of habitat.

**Bibliography.** Anon. (1999), Araya & Chester (1993), Canevari *et al.* (1991), Chebez *et al.* (1999), Clark (1986), Cofré (1999), Fjeldså & Krabbe (1990), Grigera *et al.* (1996), Hackenberg (1989), Humphrey *et al.* (1970), Johnson (1967), Mazar Barnett & Pearman (2001), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Olrog (1968), de la Peña (1994), Pereyra (1950), Short (1970a, 1985b), Stoltz *et al.* (1996), Vuilleumier (1985).

## 181. Imperial Woodpecker

### *Campephilus imperialis*

French: Pic impérial

German: Kaiserspecht

Spanish: Picamaderos Imperial

**Taxonomy.** *Picus imperialis* Gould, 1832, "California" = Jalisco, Mexico.

Forms a superspecies with *C. principalis*. Monotypic.

**Distribution.** W Mexico in Sierra Madre Occidental, from W Sonora and Chihuahua S to Jalisco and Michoacán (probably extinct).

**Descriptive notes.** c. 56-60 cm. World's largest woodpecker; huge, with pointed crest. Male has side of crown back to underside of crest and nape red, feathers with white bases; rest of head and neck, also upperparts, underparts and tail, black, with blue gloss on head, neck and upperparts, narrow white line down each side of mantle; upperwing black, coverts glossed blue, inner primaries tipped white, secondaries and tertials all white apart from black bases; underwing as above, but lesser and median coverts and primary coverts also white, with a few black spots or bars; very long bill chisel-tipped, culmen slightly curved, broad across

nostrils, ivory-white to ivory-yellow; iris pale yellow; legs grey. Distinguished from *C. principalis* by larger size, no white stripes on neck. Female as male, but no red on head, even longer crest curving strongly upwards and forwards. Juvenile duller, browner, than adult, unglossed, with white tips to all flight-feathers, somewhat less white in secondaries, eyes greyish, both sexes initially without red on head and with very long crest, red soon appearing on rear of male's head. Voice. Calls sounding like toy trumpet.

**Habitat.** Found in oak-pine (*Quercus-Pinus*) forest belt of mountains, in extensive park-like stands of large pines (*Pinus*) containing many dead trees. Recorded from 1670 m up to 3050 m, but mostly above 1900 m.

**Food and Feeding.** Presumably large beetle larvae (Cerambycidae). In pairs and in family groups of 3-4 birds, occasionally larger groups. Main foraging technique is scaling bark from dead trees, and excavating deeply; same tree sometimes revisited over prolonged period of time. Occasional clinging upside-down, and foraging on underside of branches.

**Breeding.** Laying Feb-Jun. Nest-hole excavated high up in trunk of dead tree. Clutch generally 2 eggs (1-4). No other relevant information. Groups seem to roost in neighbouring holes. Apparent nest competitors are large parrots.

**Movements.** Resident; probably rather nomadic within habitat.

**Status and Conservation.** CRITICAL. CITES I. Restricted-range species; present in Sierra Madre Occidental and Trans-Mexican Range EBA. Probably extinct. No confirmed reports since 1958, when it was seen in the state of Durango. A number of claimed sightings include several post-1965 reports; in particular, a solitary female alleged to have been seen in N Sonora in 1993, a pair in C Durango in same year, and a single male c. 20 km from latter site two years later. Were any still left, however, remaining habitat is so fragmented that they would have little chance of continued survival; none seen during a year-long survey of pine forests of NW Mexico in 1994 and 1995. Seems never to have been particularly common, with estimated maximum population of no more than c. 8000 individuals; indiscriminate shooting and habitat destruction over many decades have led to its almost certain recent extermination. A single pair would probably need an area of at least 25 km<sup>2</sup> in order to forage and to breed successfully; moreover, since food (large larvae) probably available only for restricted periods, and at different times in different parts of forest, it is likely that small groups need to wander widely to be able to exploit these resources; a group of c. 8 birds could require at least 98 km<sup>2</sup> of continuous old-growth forest, and such extensive stands no longer exist. In fact, there is now no continuous area of old-growth forest remaining anywhere in the Sierra Madre Occidental that is large enough to support a single breeding pair of this picid. Centuries of hunting, for sport and because parts of this bird were thought to have useful medicinal properties, followed by the complete degradation and destruction of the habitat, have ensured that the species' dwindling numbers continued to fall to unsustainable levels. No reserve has ever been established with the aim of protecting this unique woodpecker, and it is now too late.

**Bibliography.** Anon. (1996b, 1998b), Baieich & Harrison (1997), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fleming & Baker (1963), Friedmann *et al.* (1957), Howell & Webb (1995), King (1978/79), Knox & Walters (1994), Lammertink (1996), Marshall (1957a), Miller *et al.* (1957), Nelson (1988), Peterson & Navarro-Sigüenza (2000), Plimpton (1977), van Rossem (1945), Short (1985b), Smith (1908), Stattersfield & Capper (2000), Stoltz *et al.* (1996), Tanner (1964), Wege & Long (1995).

## 182. Ivory-billed Woodpecker

### *Campephilus principalis*

French: Pic à bec ivoire

German: Elfenbeinspecht

Spanish: Picamaderos Picomarfal

**Other common names:** Northern Ivory-billed Woodpecker (*principalis*); Cuban Ivory-billed Woodpecker (*bairdii*)

**Taxonomy.** *Picus principalis* Linnaeus, 1758, South Carolina, USA.

Forms a superspecies with *C. imperialis*. Race *bairdii* considered possibly a separate species by some. Two subspecies recognized.

**Subspecies and Distribution.**

*C. p. principalis* (Linnaeus, 1758) - SE USA (probably extinct).

*C. p. bairdii* Cassin, 1863 - Cuba (probably extinct).

**Descriptive notes.** 48-53 cm; c. 450-570 g. Extremely large, distinctive woodpecker. Male has side of crown back to underside of crest, rear of head and nape red, with paler feather bases; rest of head and neck black, white stripes from lower edge of rear ear-coverts and down neck sides and along mantle sides meeting in centre of back; rest of upperparts black, glossed blue; upperwing black, coverts glossed blue, inner primaries tipped white, secondaries and tertials all white apart from black bases; uppertail black, occasionally some white spots in outer tail; underparts black to brownish-black, sometimes vague pale barring on flanks; underwing as above, but lesser and median coverts and primary coverts also white, usually a few black spots or bars on primary coverts; long bill chisel-tipped, slightly curved on culmen, broad across nostrils, ivory-white to creamy; iris white to creamy; legs grey. Female is slightly smaller than male, has somewhat longer crest sometimes slightly upcurved, no red on head. Juvenile browner, less glossy than adult, crest shorter, white tips to all primaries but less white on underwing, eyes brown, head pattern of both sexes as adult female, male gradually acquiring red over 3 months. Race *bairdii* differs from nominate in slightly shorter and narrower bill, and white neckstripe extending a little farther forwards along lower edge of ear-coverts. Voice. Common note when alarmed "kent" or "hant", timbre like clarinet or toy trumpet, repeated up to 6 times; low conversational notes between pair-members; nestlings initially utter weak buzz, later a louder chirp. Instrumental signal of single or double raps; tapping at or inside nest.

**Habitat.** Heavy forest in often inaccessible hardwood and cypress swamps; originally, probably mainly pine (*Pinus*) forest with many dead trees. Lowland forest and mountain forest in Cuba, more recently in pine (*P. cubensis*) forest. Presence of many dead trees, especially fire-killed ones, important. **Food and Feeding.** Chiefly large larvae of wood-boring beetles (Cerambycidae, Buprestidae, Scolytidae, Elateridae, Eucnemidae), which also fed to young; fruits, berries and nuts also taken. Forages at low to upper levels; rarely, if ever, on ground. Dead trees, e.g. fire-killed pines, or dead parts of live trees, favoured feeding sites. Removal of bark from dead trees with blows of bill a very common feeding technique; deep pits also produced, similar in size to those made by *Dryocopus pileatus*. From a few minutes to up to half an hour spent at a single site.

**Breeding.** Jan-Apr in USA; Mar-Jun in Cuba, with peak in Apr. Displays with crest-raising, possibly also head-swinging. Nest excavated in large dead or dying tree, occasionally in palm in Cuba, at 8-15 m, entrance hole more or less vertically oval or drop-shaped, minimum of 8-9 cm in diameter, height 14-6 cm, rarely 17 cm, width up to 12 cm. Clutch 2-4 eggs; incubation by both sexes, only male at night, period c. 20 days; both also feed chicks, directly, male apparently does most of brooding and nest sanitation; fledging period c. 35 days; young regularly fed by parents for at least 2 months after fledging, remain much longer in parental territory. **Movements.** Resident.

**Status and Conservation.** CRITICAL. Probably extinct. Last confirmed records in USA in 1950's, although possibly still survived there in 1970's. Since then, intermittent reports from SE parts of country always found to refer to superficially similar but much smaller *Dryocopus pileatus*. Pair said to have been seen in 1999 in Pearl River Wildlife Management Center, Louisiana, but not found in follow-up surveys; further surveys under way in early 2002. Was once widely distributed in SE USA, from Oklahoma and Missouri across to North Carolina and S to Texas and Florida, prime habitat being tall lowland swamp-forest. Occurred at low densities, maximum in USA 0.006 pairs/10ha, with 1 pair requiring at least 16 km<sup>2</sup> of suitable habitat. Destruction and fragmentation of its habitat caused massive decline in numbers; even by 1940's the species had been reduced to a very small number of individuals, and forests have continued to be destroyed since then. Interactions with *Dryocopus pileatus* may also have been detrimental to declining populations. Similarly, much of the forest inhabited by race *bairdii* in Cuba had gone by start of 20th century, and it was confined to a few surviving tracts of Cuban pine forest in E of island. In 1948, a population was discovered in the Cuchillas de Moa Mts, and 6 territories were located there in 1956, in which year 8 pairs and 1 juvenile were found in E Cuba; political problems prevented further field research until 1985, by when much of the region's forest had been removed, and the species was not seen. Further expeditions in 1986 located 1 bird at Ojito de Agua and a pair at Cabezada del Yarey; by 1991 only a single bird appeared to be left; in 1992 and 1993, intensive fieldwork in E Cuba failed to locate any individuals. With insufficient old-growth forest remaining in the ranges of both races, it seems highly unlikely that this woodpecker still survives. The only realistic hope seems to lie in an area of apparently undisturbed pine forest high in the Sierra Maestra (SE of original range in E Cuba); indeed, the species was reported there in 1998, but with no subsequent confirmation.

Tribe PICINI

Genus *PICUS* Linnaeus, 1758

183. Banded Woodpecker

*Picus miniaceus*

**French:** Pic minium      **German:** Mennigspecht      **Spanish:** Pito Miniado  
**Other common names:** Banded Red Woodpecker

**Taxonomy.** *Picus miniaceus* Pennant, 1769, highlands of Java.  
Species name sometimes misspelt *mineaceus*, and in past *miniatus*, but original spelling is *miniaceus*.  
Proposed race *dayak* (Landak, Borneo) inseparable from *malaccensis*. Four subspecies recognized.  
**Subspecies and Distribution.**  
*P. m. perlutus* (Kloss, 1918) - S Myanmar (S Tenasserim) and peninsular Thailand.  
*P. m. malaccensis* Latham, 1790 - Peninsular Malaysia, Sumatra (including Bangka and Belitung) and Borneo.  
*P. m. niasensis* (Büttikofer, 1897) - Nias I (off NW Sumatra).  
*P. m. miniaceus* Pennant, 1769 - Java.

**Descriptive notes.** 23-26 cm; 79-102 g. Male has reddish-brown forehead, dull red crown to nape, thin elongated crest feathers yellow at tips; sides of head and neck dark brown, reddish feather tips; brown chin and throat usually tipped rufous; dull red above, mantle and back barred buff, rump yellow, uppertail-coverts olive-brown with buff barring; wing-coverts dull red; flight-feathers brown, extensively dull olive-red on outer webs of primary bases, secondaries and tertials, barred buffish on outer webs and base of inner webs of primaries and inner webs of secondaries; uppertail blackish; rufous-brown upper breast with faint barring, pale speckles, whitish-buff to pale rufous rest of underparts narrowly barred dark brown; brown underwing barred buff, in worn plumage, red areas browner, pale barring on upperparts less obvious; shortish bill slightly chisel-tipped, curved on culmen, fairly broad across nostrils, very broad at base, dark grey, paler lower mandible; iris dark chestnut to red; legs green-grey. Female is slightly smaller than male, with proportionately longer tail, face and throat browner with few red tips, pale buffish speckling. Juvenile duller than adult, more obscure barring below, male with red on crown and nape, female red only on hindcrown. Race *perlutus* is dull greenish-olive above, has more extensive yellow on crest, less patterned breast, on average shorter bill; *malaccensis* is very like previous, but dark bars below broader; *niasensis* is slightly smaller than last, brighter, with red mantle feathers, red extending to upper breast. Voice. Single "keek"; mournful descending "kwee" or "peew" in series of up to 7, as territorial call; "kwi-wi-ta-wi-kwi" series during encounters.

**Habitat.** Mainly dense primary (dipterocarp) evergreen forest; also secondary growth, forest edge and open woods, including rubber plantations, gardens and mangroves at lower altitudes. Lowlands to montane habitats, usually below 900 m but occasionally to 1200 m in SE Asia; to 1500 m in Java, and to 1400 m, possibly 1700 m, in Borneo.  
**Food and Feeding.** Ants and their eggs and larvae. Singly or in pairs, unobtrusive; partners may feed close together. Forages at all levels. Searches for food among vines and dense branches, on large-diameter trunks, particularly of dead trees, and on fallen logs; visits branches, decayed stubs and bases of epiphytes in canopy. Main techniques are light tapping, also probing and gleaning. Movements slow and deliberate; may pause to scan surroundings. Considerable periods spent in exploiting single sites.  
**Breeding.** Nov-Sept. Both sexes excavate nest-hole, in decayed tree or in dead or rotten part of live tree. Displays include crest-raising, swinging movements of head and body; gliding and floating flight interspersed with weak fluttering, by male in presence of female. Clutch 2 or 3 eggs; incubation and fledging periods not documented; both parents feed chicks. Often only 1 young fledges.  
**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common; rather uncommon in N of range; more frequent in S, common in Peninsular Malaysia and Singapore; rare in Java.  
**Bibliography.** Andrew (1992), van Balen (1999), Bucknill & Chasen (1990), Chasen (1937), Duckworth & Kelsh (1988), Dupond (1942), Dymond (1994), Edgar (1933), Grantham (2000), Hails & Jarvis (1987), Hellebrekers & Hoogerwerf (1967), Holmes (1994), Inskipp *et al.* (1996), Jepson & Brinkman (1993), Jeyarajasingam & Pearson (1999), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Phillips (1993), Madoc (1976), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Nash & Nash (1985), Robinson & Kloss (1919a), Robson (2000), Sargeant (1997), Short (1973d), Smythies (1986, 1999), Vowles & Vowles (1997), Wells (1985, 1990, 1999), Wong (1985).

184. Lesser Yellownappe

*Picus chlorolophus*

**French:** Pic à huppe jaune      **German:** Gelbhaubenspecht      **Spanish:** Pito Crestigualdo  
**Other common names:** Lesser/Small Yellow-naped Woodpecker; Ceylon Yellow-naped Woodpecker (*wellsi*)

**Taxonomy.** *Picus chlorolophus* Vieillot, 1818. Bengal.  
Forms a superspecies with *P. puniceus*, which is separated altitudinally in small area of range overlap. Considerable variation, both individual and geographical, and races also intergrade; proposed races *chlorolophoides* (N Thailand), *laotianus* (Laos) and *krempfi* (Cochinchina) considered not acceptable. Nine subspecies recognized.  
**Subspecies and Distribution.**  
*P. c. similae* Meinertzhagen, 1924 - N India (Himachal Pradesh) E to W Nepal.  
*P. c. chlorigaster* Jerdon, 1844 - peninsular India.  
*P. c. wellsi* Meinertzhagen, 1924 - Sri Lanka.  
*P. c. chlorolophus* Vieillot, 1818 - E Nepal E to Myanmar and N Vietnam.

*P. c. annamensis* Meinertzhagen, 1924 - SE Thailand to S Vietnam.  
*P. c. citrinocristatus* (Rickett, 1901) - N Vietnam (Tonkin) and SE China (Fujian).  
*P. c. longipennis* (Hartert, 1910) - Hainan I.  
*P. c. rodgeri* (Hartert & Butler, 1898) - W Malaysian highlands.  
*P. c. vanheysti* (Robinson & Kloss, 1919) - Sumatran highlands.

**Descriptive notes.** 25-28 cm; 57-74 g (*chlorigaster*), 74-83 g (*similae*). Male has green forehead and crown bordered with red feather tips, golden-yellow or orange on crest and hindneck; olive-green ear-coverts and neck side, usually small area of white just behind upper corner of eye; upper lores black, lower lores to below lower edge of ear-coverts white, streaked olive; red malar stripe with some olive-green feather bases usually showing; olive to greyish chin and throat variably marked with white streaks or bars, throat pattern very variable, sometimes mainly whitish but can be all dark; green upperparts tinged golden-yellow, rump often brighter; outer webs of secondaries and of inner primaries rufous, edged green (rufous more prominent when wings worn), rest of primaries and inner webs of secondaries dark brown with white bar-like spots; uppertail blackish, outer feathers washed green; lower throat and breast grey-green to dark green, belly to undertail-coverts off-white with slightly diffuse olive to olive-grey or brownish-olive chevrons; underwing brownish, olive coverts, barred whitish; fairly long bill almost straight, chisel-tipped, broad across nostrils, blackish-grey, paler, yellower base of lower mandible; iris red-brown to dark red, orbital skin greyish; legs grey-green. Female is slightly smaller than male, lacks red in malar, has red of crown confined to small patch at rear sides. Juvenile duller above, more barred on breast, with less red on crown than respective adult. Races differ mainly in tone of upperparts, pattern of underparts, and size: *similae* is largest, with longer wings and longer tail than nominate, greener, less yellow, above, nape less golden; *annamensis* is smaller than nominate, darker green above, with more red on crown, whiter lower underparts, barring reaching to lower breast but more obscure on belly and flanks; *chlorigaster* is smaller than previous races, lacks white on face, has more red but less yellow on head, is darker green above with more red on wings, dull olive-green below with pale bar-like spotting on flanks and belly, pale spots on breast; *wellsi* is somewhat darker than last, with even more red on crown, wings with slightly more rufous, reduced pale markings below; *rodgeri* resembles previous but not quite so dark above, has prominent pale cheekstripe, less red on crown, slight golden tinge on crest, more bars below; *vanheysti* resembles last, but somewhat yellower above, greener, less grey, below; *citrinocristatus* lacks red malar, has upperparts only slightly yellow-tinged, underparts sooty-grey with paler bars on flanks, brighter lemon-yellow nape; *longipennis* is slightly smaller than previous, with stronger green tinge below, flanks more barred. Voice. Loud, mournful, "pée-a" or "pée-ui", also short "chak"; up to 10 "kwee" notes in slow, slightly descending series; low chuckling noises in close intersexual confrontations. Drums occasionally.

**Habitat.** Evergreen forest and moist deciduous forest, dry forest, woodland, bamboo, scrub, plantations, and well-wooded gardens. Habitats most diverse in India, especially where no other congeners occur. From lowlands and foothills to 1800 m; to c. 2100 m in Sikkim and Nepal (common only to 1750 m); above 900 m in Peninsular Malaysia; 800-1400 m in Sumatra. Replaces *P. puniceus* at higher altitudes.  
**Food and Feeding.** Ants, including *Crematogaster*, also beetles and their larvae (including dung beetles); other insect larvae. Also takes berries and nectar. Forages singly, in pairs, or in small family groups; regularly joins mixed-species flocks, particularly with babblers (Timaliidae), drongos (Dicruridae) and other insectivores, or other woodpeckers. Forages in smaller trees, in undergrowth, often on fallen logs and dead trees in windthrow areas. Seems usually to prefer trunks and larger branches, but also moves along thin branches to reach arboreal nests of ants, or to probe at flowers. Forages commonly on ground, even seeks insects in dung pats. Gleaning and probing are the main foraging techniques; excavating with pecking and hammering infrequent. Movements are slow, except when accompanying other species. Can spend much time at a single site.  
**Breeding.** Feb-Jul, mainly Mar-May. Crest-raising in display. Nest excavated by both sexes in (partly) dead trunk or branch, at 1.5-20 m, mostly below 5 m. Usually 3-4 eggs (2-5), clutches smaller in S; both sexes incubate, and both feed chicks, by regurgitation; incubation and fledging periods unknown.  
**Movements.** Resident. Possible dispersal; recorded as rare vagrant in NE Pakistan.

**Status and Conservation.** Not globally threatened. Common to fairly common, or locally common, throughout most of range; common in SE Asia; uncommon in China. Occurs in numerous protected areas in all parts of range. Adaptable; able to thrive in secondary habitats.  
**Bibliography.** Ali (1996), Ali & Ripley (1983), Ali *et al.* (1996), Andrew (1992), Bangs & Van Tyne (1931), Bets (1934), Biswas (1961a), Bromley (1952), Chasen & Hoogerwerf (1941), Chazee (1994), Deignan (1945), Delacour (1951b), Eames & Robson (1992), Éthécopar & Huc (1978), Evans & Timmins (1998), Goes (1999), Grimmer *et al.* (1998), Harrison (1999), Harvey (1990), Henry (1998), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Jeyarajasingam & Pearson (1999), King & Rappole (2001), Kloss (1931), Lamfuss (1998), Lekagul & Round (1991), Ludlow (1937, 1944), MacKinnon & Phillips (1993, 2000), Madoc (1976), van Marle & Voous (1988), Medway & Wells (1976), Meyer de Schauensee & Ripley (1940), Parrott & Andrew (1996), Phillips (1978), Proud (1958), Rand & Fleming (1957), Riley (1938), Ripley (1982), Roberts (1991), Robson (2000), Santharam (1997, 1998c), Shankar Raman (2001), Short (1973d), Smythies (1986), Stepanyan (1995), Wells (1999), Zhao Zhengjie (1995).

185. Crimson-winged Woodpecker

*Picus puniceus*

**French:** Pic grenadin      **German:** Rotflügelspecht      **Spanish:** Pito Alirrojo  
**Other common names:** Crimson-winged Yellownappe

**Taxonomy.** *Picus puniceus* Horsfield, 1821, Java.  
Forms superspecies with *P. chlorolophus*; separated altitudinally in small area of overlap. Proposed race *continentalis* (Malay Peninsula) merely averages slightly larger. Three subspecies recognized.  
**Subspecies and Distribution.**  
*P. p. obscurandus* (Hartert, 1896) - S Myanmar (S Tenasserim) and peninsular Thailand S to Sumatra (including Bangka) and Borneo.  
*P. p. soligae* Meyer de Schauensee & Ripley, 1940 - Nias I (off NW Sumatra).  
*P. p. puniceus* Horsfield, 1821 - Java.  
**Descriptive notes.** c. 25 cm; 66-96 g. Male has dark red forehead to hindcrown, often dark olive feather bases showing through, elongated crest of red feathers, yellow under crest and down hindneck;

Chuchi Reserve (Thailand), Taman Negara National Park (Peninsular Malaysia), Way Kambas National Park (Sumatra) and Mount Kinabalu National Park (Borneo).  
**Bibliography** Andrew (1985, 1992), van Balen (1999), Bucknill & Chasen (1990), Castelletta *et al.* (2000), Duckworth & Kelsh (1988), Duckworth *et al.* (1997), Grantham (2000), Hellebrekers & Hoogerwerf (1967), Inskipp *et al.* (1996), Jepson & Brinkman (1993), Jeyarajasingam & Pearson (1999), Kloss (1931), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Philipps (1993), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Meyer de Schauensee & Ripley (1940), Robinson & Kloss (1924a), Robson (2000), Sargeant (1997), Short (1973d), Smythies (1986, 1999), Vowles & Vowles (1997), Wells (1985, 1999), Wilkinson, Dutton & Sheldon (1991), Wong (1985).

188. Streak-breasted Woodpecker

*Picus viridanus*

**French:** Pic verdâtre      **German:** Burmagrünspecht      **Spanish:** Pito Verdoso  
**Other common names:** Burmese/Small/Little Scaly-bellied (Green) Woodpecker

**Taxonomy.** *Picus viridanus* Blyth, 1843, Arakan, Myanmar. Forms a superspecies with *P. vittatus*. Has often been considered conspecific, but appears to be separated by habitat, although some possible overlap in this respect; further study needed. Birds from Thai-Malay Peninsula described as race *weberi*, being slightly smaller and darker, but differences insignificant and probably due to clinal variation. Monotypic.

**Distribution.** SW & SE Myanmar and SW Thailand S to extreme NW Peninsular Malaysia.  
**Descriptive notes.** 30-33 cm; c. 90-120 g. Male has red forehead to nape and slight crest, black base of forehead, upper lores and narrow line bordering crown; thin white supercilium back to nape; lower lores and ear-coverts off-white to greyish, ear-coverts streaked dark; white-streaked black malar stripe, pale brown chin and throat, throat usually with tinged green or olive and variably streaked white; bronzy yellow-green hindneck and neck sides; bronze-green upperparts, dull yellow-green rump, olive-green uppertail-coverts; blackish-brown flight-feathers, bronze-green on outer webs of secondaries, narrow pale buff-white bars on inner webs of all feathers, also on outer webs of primaries; uppertail blackish, poorly defined brownish bars; olive-green below, paler towards rear, with whitish or buff feather edges, tips and central streak producing bold scaly pattern; whitish undertail-coverts streaked dark olive; underwing brownish, barred whitish, coverts white with olive barring; longish bill fairly broad-based, slightly chisel-tipped, dirty yellowish, lower mandible paler, blackish culmen and tip; iris reddish-brown to red; legs grey-green. Distinguished from *P. vittatus* by darker throat, duller breast, more bronzy upperparts. Female is slightly shorter-billed than male, has entire forehead to nape black. Juvenile duller than adult, more diffusely marked below, often with stronger tail barring, male with orange-red on crown. Voice, Explosive "kirrr", "tcheu-tcheu-tcheu-tcheu" series.

**Habitat.** Broadleaved evergreen forest, mangroves, coastal scrub. Lowlands.  
**Food and Feeding.** Ants. Commonly forages on the ground; also on moss-covered trees and boulders.  
**Breeding.** Feb-Apr. Nest-hole excavated in tree. Clutch 4 eggs. No other information.  
**Movements.** Resident.  
**Status and Conservation.** Not globally threatened. Uncommon, locally fairly common; possibly overlooked. Occurs in Kaeng Krachan National Park and Khao Nor Chuchi Reserve (Thailand). Has a very small range, within which it appears to have fairly strict habitat requirements. Could be adversely affected by increased forest destruction. Research required on its ecology and breeding biology; taxonomic study also desirable.  
**Bibliography.** Baker (1919), Deignan (1955), Inskipp *et al.* (1996), Jeyarajasingam & Pearson (1999), Kloss (1926), Lekagul & Round (1991), Riley (1938), Robson (2000), Smythies (1986), Wells (1999), Wheatley (1996).

189. Laced Woodpecker

*Picus vittatus*

**French:** Pic médiastin      **German:** Netzbauchspecht      **Spanish:** Pito Colinegro  
**Other common names:** Laced Green Woodpecker, Small Scaly-bellied (Green) Woodpecker

**Taxonomy.** *Picus vittatus* Vieillot, 1818, Java. Forms a superspecies with *P. viridanus*. Sometimes considered conspecific, but may be separated by habitat, although some possible overlap in this respect; further study needed. S & E populations tend to have more bronze tinge on upperparts, and rump colour tends more towards orange in E, but much individual variation, and racial separation unwarranted. Proposed races *eisenhoferi* (N Thailand), *connectens* (Langkawi I, off NW Peninsular Malaysia) and *limitans* (Kangean I) considered unacceptable. Monotypic.  
**Distribution.** E Myanmar E to extreme SC China (S Yunnan) and N Vietnam (N Annam), and S to S Thailand, Cochinchina, W & S Peninsular Malaysia. E Sumatra (including Lingga Archipelago), Java, Bali and Kangean Is.

**Descriptive notes.** 30-33 cm; 94-132 g. Male has red forehead to crown and short crest, bordered by thin black line; narrow white eyering and short supercilium; pale greyish to buffish ear-coverts often tinged bluish, faintly streaked brown; lower lores buffy or whitish, extending into diffuse pale cheekstripe; black malar area usually with a few small white streaks or spots; plain whitish-buff to pale yellow-green or yellow chin and throat; hindneck, neck side and upperparts yellow-green, rump more yellowish; blackish-brown flight-feathers, outer webs of secondaries bronze-green, narrow pale buff-white bars on inner webs of all feathers, also on outer webs of primaries; uppertail blackish, usually a few thin pale bars on outer feathers, sometimes also central feathers; breast buffish-yellow or olive-buff, lower breast to vent buffy to greenish-white with scaly pattern of olive-green submarginal markings on both webs; underwing-coverts yellow-white, barred brown; undertail as above but paler, outer feathers often tinged dull yellow; longish bill fairly broad-based, somewhat chisel-tipped, curved culmen, blackish, lower mandible

dull yellow with darker tip; iris red-brown or red; legs grey-green. Distinguished from *P. viridanus* by paler throat, yellow breast, more distinct black malar stripe, less bronzy upperparts. Female is slightly shorter-billed than male, has forehead to nape black. Juvenile duller, with underpart markings more diffuse, usually some streaking on throat, tail more clearly barred, male with orange-red crown. Voice, Call "keep" or "kee-ip"; long series of "kew" notes as territorial call, very like *P. canus* but lower-pitched, shorter, delivered in faster succession; loud or low "wick, a-wick, a-wick" series in close encounters. Drums in short steady rolls.

**Habitat.** Deciduous forest, evergreen forest, secondary growth, bamboo, plantations, and village and suburban gardens; rather open coastal forest and scrub, including casuarinas, mangroves and coconut plantations. Where overlaps with *P. viridanus* in W & SW Thailand, mainly restricted to mangroves, drier deciduous woodland and coastal scrub, rarely in gardens. From sea-level to 200 m in Greater Sundas, to 1500 m in SE Asia.  
**Food and Feeding.** Beetles and flies. Occurs singly or in pairs, partners keeping in close contact. Forages on ground, on fallen trees, as well as in bamboo and trees. In trees prefers the trunk or larger branches, staying low in mangroves; prefers the bases of fronds in palms; on bamboo, pays particular attention to nodes. Techniques include vertical and lateral pecking, probing; on the ground, sweeps away debris, and probes into soil or, in mangroves, mud.

**Breeding.** Feb-Jul; in Jan, Apr and Sept in Java. Crest-raising a common display; swinging movements also occur. Nest-hole excavated at 0.5-9 m in tree. Clutch 3 or 4 eggs; no further details available.

**Movements.** Resident.  
**Status and Conservation.** Not globally threatened. Locally common; uncommon in Singapore; rare in Java. Occurs in several protected areas, e.g. Kaeng Krachan National Park (Thailand), Kuala Selangor Reserve (Malaysia), Nam Bai Cat Tien National Park (Vietnam), Sungai Buloh Nature Park (Singapore) and Aas Purwo National Park (Java). Has declined greatly in Sumatra due to loss of habitat.  
**Bibliography.** Andrew (1992), Baker (1919), van Balen (1999), Bucknill & Chasen (1990), Chasen (1935), Deignan (1945, 1955), Eames & Robson (1992), Edgar (1933), Grantham (2000), Grimmer *et al.* (1998), Hails & Jarvis (1987), Harvey (1990), Holmes (1996), Inskipp *et al.* (1996), Jeyarajasingam & Pearson (1999), Kloss (1926), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Philipps (1993, 2000), Madoc (1976), van Marle & Voous (1988), McClure (1998), Medway & Wells (1976), Mees (1996), Meyer de Schauensee & Ripley (1940), Paynter (1970), Riley (1938), Robinson & Kloss (1919a), Robson (2000), Robinson *et al.* (1993a), Sargeant (1997), Short (1973d), Smythies (1986), Stepanyan (1995), Stresemann (1921a), Van Tyne & Koeltz (1936), Wells (1990, 1999), Zhao Zhengjie (1995).

190. Streak-throated Woodpecker

*Picus xanthopygaeus*

**French:** Pic striolé      **German:** Hindugrünspecht      **Spanish:** Pito Culigualdo  
**Other common names:** Little Scaly-bellied (Green) Woodpecker

**Taxonomy.** *Brachylophus xanthopygaeus* J. E. Gray and G. R. Gray, 1846, Himalayas and central India. Species name sometimes erroneously given as *P. myrmecophoneus*, a junior synonym. Monotypic.  
**Distribution.** N and peninsular India and lower foothills of Himalayas in S Nepal E to Myanmar and S China (W Yunnan), and S to Sri Lanka, SW Thailand; also Cambodia, S Laos and Cochinchina.

**Descriptive notes.** 30 cm; 83-111 g. Male has red forehead to hindcrown with dark variable amount of black at borders, thin white supercilium, greyish ear-coverts streaked brownish, narrow white cheekstripe, blackish malar stripe greatly obscured by pale whitish tips and edges; whitish chin and throat with variable fine dark brown or olive streaks; hindneck and upperparts yellowish-green, rump and most of uppertail-coverts bright yellow (sometimes some orangey feathers admixed); dark green wing-coverts and tertiaries, tertiaries sometimes with few white bars at base; brownish-black flight-feathers, outer webs of

secondaries dark green, white bars on inner webs of secondaries and both webs of primaries; uppertail blackish, narrowly barred brown; whitish to pale buff-white below, tinged green on breast, feathers with broad olive edges and tips and occasionally shaft streaks, forming distinct scaly pattern, sometimes more diffuse on lower belly; whitish undertail-coverts with dark arrowheads; underwing brownish, coverts paler, all barred white; undertail dark brown, washed dull yellow, variable dull yellow-brown bars; longish bill broad-based, slightly chisel-tipped, slightly curved culmen, dark brown or grey-brown, dull yellow base of lower mandible; iris white or pale pinkish, darker outer area; legs grey-green. Distinguished from very similar *P. viridanus* by pale eyes, more obvious pale cheekstripe, streaked throat, more streaky breast, slightly paler ground colour and less scaly appearance below. Female has forehead to nape black with greyish streaking. Juvenile less yellow-tinged above, grey feather bases creating more variegated appearance, less scaly-looking below, male with less red on head than adult. Voice, Sharp single "queemp" and drumming the only acoustic signals reported.

**Habitat.** Open deciduous forest, dry dipterocarp forest, also semi-evergreen, sal (*Shorea*) and mixed bamboo forests; occurs also in secondary growth, sparsely wooded park-like country, teak and particularly rubber plantations, and tea estates. Avoids dense forest. Lowlands and lower hills, to 500 m; to 450 m, rarely over 900 m, in Nepal, but reported at up to 1700 m in Himalayan foothills; to 1500 m in Sri Lanka.  
**Food and Feeding.** Ants, termites (Isoptera) and other small insect larvae; flower nectar and seeds also taken. Generally solitary. Forages frequently on ground, and may climb over boulders. Little known.  
**Breeding.** Jan-May in India, Apr-Sept in Sri Lanka, and Mar-May in SE Asia. Nest-hole excavated by both sexes, sometimes very low (0.6 m) but usually at c. 4-8 m, in tree trunk or large branch, cavity c. 30 cm deep. Clutch 3-5 eggs; both parents feed chicks; no information on incubation and fledging periods.  
**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common in much of Indian Subcontinent, but rare and local in Bhutan, Bangladesh and Sri Lanka; uncommon to scarce in Myanmar and Thailand, very rare in Yunnan; few recent records from Indochina, where current status uncertain. Occurs in several protected areas, e.g. Corbett, Kaziranga and Mudumalai National Parks (India) and Chitwan National Park (Nepal). Poorly known; research needed to determine true status.  
**Bibliography.** Ali (1969, 1996), Ali & Ripley (1983), Barua & Sharma (1999), Biswas (1961a), Delacour & Jabouille (1940), Duckworth *et al.* (1999), Evans & Timmins (1998), Grimmer *et al.* (1998, 2000), Harrison (1999), Harvey (1990), Henry (1998), Hoffmann (1998), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Kazmierczak (2000), Lamsfuss (1998), Lekagul & Round (1991), MacKinnon & Philipps (2000), Mohan (1997), Mukherjee (1995), Philipps (1978), Prasad & Madhusudan (1993), Riley (1938), Ripley (1982), Robson (2000), Round (1988), Santharam (1998c), Shrestha (2000), Thewlis *et al.* (1998), Zhao Zhengjie (1995).

191. Scaly-bellied Woodpecker

*Picus squamatus*

**French:** Pic écaillé      **German:** Schuppengrünspecht      **Spanish:** Pito Escamoso  
**Other common names:** Common/Large Scaly-bellied Woodpecker, Scaly-bellied Green Woodpecker, Great Scaly Woodpecker

**Taxonomy.** *Picus squamatus* Vigors, 1831, Simla-Almora district, western Himalayas. Two subspecies recognized.  
**Subspecies and Distribution.**  
*P. s. flavirostris* (Menzbier, 1886) - Afghanistan (except NE) and W Pakistan.  
*P. s. squamatus* Vigors, 1831 - NE Afghanistan E to Darjeeling.

**Descriptive notes.** c. 35 cm; 156-194 g. Male has red forehead, crown and nape, usually some dark feather bases showing through (especially when worn), more orangey in narrow wedge down hindneck; black upper lores and narrow line along crown side, white supercilium from above eye to side of nape, narrow black eyestripe; lower lores yellowish-white, cheeks and ear-coverts olive-grey, greener or yellowish on neck side; black malar stripe streaked whitish; olive chin, throat and breast, variably grey-tinged; green upperparts, yellow on rump and uppertail-coverts, latter with green bases; flight-feathers and primary coverts blackish-brown, secondaries and tertials with green outer (and part of inner) webs, all barred whitish; uppertail dark brown, barred buff-white, strong green suffusion on outer feathers; lower breast and belly greyish-white, tinged greenish, feathers with broad black submarginal lines producing strong scaly appearance, usually also thin black shaft streaks; underwing barred brown and white, coverts yellowish; undertail as above but paler, yellowish barring; in worn plumage, upperparts much greyer, duller yellow rump, breast greyer, markings below even more contrasting; long bill almost straight, slightly chisel-tipped, fairly broad across nostrils, pale horn-yellow to yellowish-grey, usually darker tip; iris pinkish-red, paler outer ring; legs greenish-grey to olive. Female is shorter-billed than male, perhaps duller green, has forehead to nape black with grey streaks. Juvenile greyer than adult, blotchy grey and dull green above, black hindneck, entire underparts with scaly pattern but markings less contrasting, eyes brownish, male with much black in red of crown. Race *flavirostris* is much paler than nominate, yellower above with more obvious barring on wings, and has whiter throat, pale olive-buff breast, yellowish belly to vent; scaling narrower and less contrasting. **Voice.** Main call, also in flight, a melodious vibrating "klee-guh klee-guh" or "kuik-kuik-kuik", rapidly repeated 3-8 times, as advertisement; also, short high-pitched "kik", more rarely a single nasal "cheenk" or "peer"; laughing calls similar to those of *P. viridis*; soft notes in close encounters between two individuals; squeaky "chissuh-chissuh" in greater excitement; nestlings give loud wheezing "chuff-chuff". Drums regularly in breeding season.

**Habitat.** Coniferous and mixed coniferous forest, and forests with temperate deciduous trees, e.g. oaks (*Quercus*) and ash (*Fraxinus*). Adaptable, found in juniper (*Juniperus*) scrub-forest, coniferous forest (*Abies spectabilis*, *Picea smithiana*), pine (*Pinus*) forest, subtropical dry deciduous forest, also in arid areas wherever tamarisk (*Tamarix*) scrub, groves, orchards or plantations provide foraging and nesting sites; also inhabits large clearings in burned forest with plenty of dead and decaying trees. Restricted to riparian woodland dominated by poplars (*Populus*) in NW of range. Frequently in orchards in winter. From 1500 m to 3700 m, locally down to 600 m, on Himalayan slopes; wanders above timber-line outside breeding season.

**Food and Feeding.** Predominantly ants and termites (Isoptera), also larvae of wood-boring insects; berries also taken in winter. Forages singly or in pairs, or in family groups. Forages by pecking and hammering on trees; regularly descends to ground, also inspects rocks. Moves on the ground by hopping.

**Breeding.** Laying late Apr to early Jun, mainly early to late May. Nest excavated by both sexes, in tree of wide range of species, including e.g. holm oak (*Quercus ilex*), pistachio (*Pistacia*), apricot, tamarisk, at 2-6 m or higher (to 15 m), or may be low down, even close to ground (30 cm), or in exposed roots in a riverbank; circular entrance hole 6 cm wide, cavity depth 30 cm; many holes sometimes started before final selection made, which may be hole from a previous year. Clutch 4-6 eggs; both sexes incubate, period 17 days; chicks fed by regurgitation, fully feathered and come to hole entrance after 2 weeks; juveniles accompanied by parents for some days after fledging.

**Movements.** Some individuals of Himalayan populations move to lower altitudes in winter. **Status and Conservation.** Not globally threatened. Common to fairly common, but rather local. Formerly extended west into Transcaspiia, but no recent records; apparently extinct W of Afghanistan. Appears to be adaptable. No obvious threats.

**Bibliography.** Ali & Ripley (1983), Bates & Lowther (1952), Borodin (1984), Christison (1941), Dementiev (1952), Dementiev *et al.* (1966), Grimmett *et al.* (1998, 2000), Hollom *et al.* (1988), Holmes (1986), Hùe & Étiéhcopar (1970), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Kazmierczak (2000), Löhr & Thieleke (1969), MacKinnon & Phillips (2000), Mathews (1941), Porter, Christensen & Schiermacker-Hansen (1996), Raja *et al.* (1999), Ripley (1982), Roberts (1991), Short (1973d), Shrestha (2000), Storrs-Fox (1943), Stradi & Hudon (1998), Stradi *et al.* (1998), Waite (1948).

192. Japanese Woodpecker

*Picus awokera*

**French:** Pic awokéra      **German:** Japangrünspecht      **Spanish:** Pito Japonés  
**Other common names:** Japanese Green Woodpecker, Wavy-bellied Woodpecker

**Taxonomy.** *Picus awokera* Temminck, 1826, Honshu. Three races often recognized: large and pale *awokera* (Honshu and nearby islands), smaller and darker *horii* (Shikoku, Kyushu, Tsushima) and smallest and darkest *takatsukasae* (Tanegashima, Yakushima). These, however, simply reflect a cline of decreasing size and increasing plumage darkness from N to S, and division into geographical races seems unjustified. Monotypic.  
**Distribution.** Japan, from Honshu S to Shikoku, Kyushu, Yakushima and Tanegashima, and including offshore islands of Tobishima, Awashima, Sado and Tsushima.

**Descriptive notes.** c. 29-30 cm; 120-138 g. Male has blackish lower forehead and lores to below eye, red from mid-forehead to nape, variable amount of black and grey feathers (especially in nape area); black malar stripe with extensive red in centre; rest of head and neck side grey, often tinged greenish when fresh, chin white to greyish-white; hindneck greyish-green; upperparts grey-green to olive-green, rump and central uppertail-coverts broadly tipped yellow, outer tail-coverts green; wing-coverts and tertials edged and tipped bronze-yellow; flight-feathers blackish-brown, outer webs of secondaries and inner primaries greenish,

white bars on inner webs of all feathers, also on outer webs of outer primaries; uppertail brown, central feathers edged green, indistinct broad yellow-brown bars; throat white, often tinged greyish, sometimes some blackish in centre of throat, breast greyish-white or pale buffish-green, belly paler, lower breast downwards with broad dark brown vermiculated barring, bars tinged greenish-olive on flanks; whitish underwing barred brown, blackish bars on coverts; fairly long bill broad-based, pointed with slightly curved culmen, overall yellowish with blackish culmen and tip; iris red; legs pale grey, tinged green or blue. Southern populations smaller and darker than northern ones. Female is slightly smaller than male, with shorter bill, has crown grey with black streaks or bars in centre, sometimes black patch, usually small red patch on nape, less red in malar. Juvenile much as adult but duller, greyer above, barring below coarser, especially on breast. **Voice.** Loud "piyo" call, also "ket, ket". Drums in quite fast rolls which are fairly long.

**Habitat.** Fairly open mixed forest in N, and evergreen forest in S; rarely in mature conifer plantations. Has recently become more common in parks and gardens. Commonest at 300-1400 m; occasionally somewhat higher in mountains, to c. 2000 m, particularly in primitive *Cryptomeris* forest on Yakushima; also descends to lowlands.

**Food and Feeding.** Chief component of diet is ants (*Lasius*, *Formica*, *Camponotus*, *Crematogaster*); other arthropods taken include Hemiptera, beetles and their larvae, and spiders. Also eats fruits, berries and seeds (*Sorbus*, *Rhus*, *Ilex*). Forages mainly at middle levels, at 2-10 m, on substrates ranging from larger branches to slender twigs; seasonal shifts in foraging preferences occur, with lower levels visited in Jan-May. Compared with *P. canus*, seems to forage little on ground (c. 20% of observations in winter). Gleaning and pecking are commonest techniques, followed by probing, and sap-drinking (winter, early spring).

**Breeding.** Apr-Jun. Nest-hole in tree at 2-4 m; also excavates holes in telephone poles (possibly only roosts). Clutch 7 or 8 eggs; no other information.

**Movements.** Moves to lower habitats in severe winters.

**Status and Conservation.** Not globally threatened. A fairly common inhabitant of hill areas and low mountains in Japan. Habit of digging holes in telephone poles can cause some problems locally, but not considered serious. Occurs in Kirishima-Yaku National Park.

**Bibliography.** Austin & Kuroda (1953), Brazil (1991), Chiba (1969), Fujii (1993), Higuchi (1980), Inskipp *et al.* (1996), Kazama (1980), King (1978/79), Nakamura *et al.* (1995), Wheatley (1996).

193. Eurasian Green Woodpecker

*Picus viridis*

**French:** Pic vert      **German:** Grünspecht      **Spanish:** Pito Real  
**Other common names:** (European) Green Woodpecker; Levallant's/Algerian (Green) Woodpecker, North African Green Woodpecker (*vallantii*); Iberian Woodpecker (*sharpei*)

**Taxonomy.** *Picus viridis* Linnaeus, 1758, Europe = Sweden. Has hybridized with *P. canus* in C Europe. Distinctive N African race *vallantii* is often treated as a full species on basis of plumage differences and possibly ecological differences, but Iberian form *sharpei*, also sometimes suggested as a separate species, effectively represents an intermediate bridge between it and nominate; further study needed. Race *karelini* intergrades with nominate. Other proposed races are *pluvius* (Britain), *frondium* (C Europe), *pronus* (Italy), *dofleini* (Macedonia), *romaniae* (Romania) and *saundersi* (Caucasus), all of which exhibit insignificant differences which come within range of variation of other races. Additional named form *bampurensis*, known only from type locality in R Bampur Basin in SE Iran (where species no longer survives), said to have particularly well-marked tailbars and heavy barring over entire lower underparts; validity and possible survival of this isolated form requires further investigation. Five subspecies recognized.

**Subspecies and Distribution.**

*P. v. viridis* Linnaeus, 1758 - Europe from Britain and S Scandinavia E to W Russia, S to France, N Balkans and Black Sea.  
*P. v. sharpei* (Saunders, 1872) - Pyrenees and Iberia.  
*P. v. karelini* J. F. Brandt, 1841 - Italy E to Bulgaria, Asia Minor, Caucasus, N Iran and SW Turkmenia.  
*P. v. vallantii* (Malherbe, 1847) - NW Morocco to NW Tunisia.  
*P. v. innominatus* (Zarudny & Loudon, 1905) - SW Iran (Zagros Mts).

**Descriptive notes.** 31-33 cm; 138-250 g (*viridis*). Male has bright red forehead to nape, usually some grey feather bases visible, especially on crown; black nasal tufts, lores and broad area around eye back to central crown side, continuing over malar region, latter with broad red stripe in centre; rear ear-coverts pale green, paler feather bases showing through, darker on neck side; chin and upper throat greyish-white, often tinged light green; hindneck and upperparts bright yellow-green, rump and uppertail-coverts bright yellow, latter with green bases usually visible, wing-coverts and tertials sometimes tinged golden or bronzy;

primaries and their coverts blackish, inner feathers edged green, white spots on both webs forming bars, secondaries golden-green on outer webs, blackish with white half-bars on inner webs; uppertail blackish, feathers edged green, faintly barred pale on central feather pair, sometimes indistinctly on others; yellow-green below, paler and more yellowish in lower regions, with fairly indistinct dark

chevrons or bars from lower flanks to undertail-coverts; underwing barred grey and white, coverts tinged yellow or green; undertail as above, outer feathers paler and more clearly barred; when worn, plumage greener and less yellow above, greyer below, flank barring more obvious, grey bases of crown feathers more extensive; long bill slightly chisel-tipped, culmen slightly curved, broad across nostrils, dark grey or blackish, paler base of lower mandible; iris white to pinkish or with pinkish outer ring; legs olive-grey. Female lacks red in moustache, flank bars may reach farther up. Juvenile distinctive, much duller, more olive, eyes duller or greyer, upperparts with whitish spots and bars, duller yellow rump barred, pale greenish underparts with dark spotting on breast and barred lower region, head spotted and streaked with grey bases in red forehead to nape, black areas duller, wings and tail more barred, male usually with narrow red tips in malar. Race *karelini* is slightly smaller and duller than nominate, less yellow, more grey; *innominatus* resembles previous, but head side and underparts very pale, almost whitish, upperparts less green, often small paler spots on mantle and scapulars, bars on wings and tail more prominent, juvenile even more strongly spotted and barred; *sharpei* is rather short-billed, resembles previous apart from facial pattern, with dusky area around eye, ear-coverts similarly greyish, thin whitish line above malar (more obvious on female), male malar almost all red with minimal black border, little or no barring below, juvenile less heavily patterned; *vallantii* is distinctive, closest to last but slightly shorter-billed, with fairly strong barring in ventral region, both sexes with all-black malar bordered above by well-marked white line, area around eyes and through ear-coverts grey-green, female with blackish-grey crown, red restricted to nape and side of hindcrown, juvenile less heavily barred and spotted than in other races. VOICE. Most calls are "kyack" or "kewk" and variations, singly or as regular or loose series; more explosive, single or repeated "kyik" in agonistic contexts; distinctive laughing, somewhat accelerating "klew-klew-klew-klew-klew", decreasing loudness, in breeding season; calls of *vallantii* thinner, more whistling, and series less regular; nestlings noisier than those of *P. canus*, with "rak-ak-ak" in presence of feeding adults. Only rarely drums, in weak and irregular bouts; drumming more frequent in N Africa (*vallantii*).

**Habitat.** Great variety of semi-open habitats; confined to larger open sections or clearings in extensively wooded areas. Forest edge, copses, parks, orchards and residential areas, usually near mature deciduous trees, but often associated with conifers in mountains and in N; requires higher proportion of deciduous trees than does *P. canus*. N Africa race *vallantii* occurs in openings and clearings of oak (*Quercus faginea*, *Q. suber*) and cedar (*Cedrus*) forests, also in pine (*Pinus*) forest. From coastal areas and lowlands to subalpine forest; to 1500 m in E Alps, to 2100 m in W Alps, and to 3000 m in Caucasus; 950-2100 m in N Africa, also lower in Morocco.

**Food and Feeding.** Predominantly ants, chiefly meadow-dwelling species of genera *Formica* (winter) and *Lasius* (spring to autumn); generally, larger ant species preferred. Various other insects also taken, also earthworms and snails; occasionally catches reptiles. Sometimes eats fruits (apples, pears, cherries, grapes), berries, rarely seeds. Lives solitarily, in pairs, and in family groups. Forages mostly on ground. Uses bill to sweep away moss, dead leaves, other debris, or snow; pecks funnel-shaped holes up to 12 cm deep in ground, and procures prey with action of the very long tongue; such holes may be exploited in lengthy and repeated visits. When snow cover heavy, can dig tunnels almost 1 m long to reach prey. Forages also on trunks and branches, as well as on buildings and rocks, by gleaning and probing. Takes sap on ringed trees, but not recorded to drill sap wells. Moves only short distances on ground.

**Breeding.** Laying from early Apr. locally Mar, to Jun; calling commences much earlier, in Dec. Male feeds female during courtship, e.g. prior to copulation. Nest excavated often at 2-10 m, sometimes to 12 m, in dead or soft living wood in unbroken tree (e.g. *Populus* favoured in Norway), work taking 2-4 weeks; entrance hole circular with diameter c. 6-4 cm, or vertically oval and 7-5 cm x 5-0 cm. Clutch usually 5-8 eggs, but 4-11 recorded; both sexes incubate, only male during the night, period 14-17 days; chicks fed by regurgitation, by both parents, fledge after 23-27 days; brood divided between parents, accompanied for 3-7 weeks.

**Movements.** Essentially resident; some local winter movements. Continental European populations disperse on average shorter distances than do *P. canus*, although extreme instances of up to 170 km recorded.

**Status and Conservation.** Not globally threatened. Common to very common throughout much of its range, but local in some parts (e.g. Turkey). Population estimates in 1980's and 1990's include 10,000-100,000 pairs (probably c.31,500) in European Russia and a further 450,000-1,360,000 pairs (probably c. 670,000) in rest of Europe; highest numbers in France, where c. 300,000 pairs. Densities not very high: maximum in France c. 0-6 pairs/km<sup>2</sup>, but in parts of N only 0-02 pairs/km<sup>2</sup>. Most populations stable or increasing, and this species has, for example, spread N into Scotland since 1950's. On the other hand, declines recorded in several European countries in recent decades: 20-30% reduction in Sweden, and since 1960's has declined by 50-75% in Netherlands. Main problems are intensification of agriculture and forestry, and conversion of pasture to arable land, which considerably reduces ant populations. Harsh winter weather can also cause major mortality, effects of which may last for years. Race *vallantii* is fairly common in Tunisia and Algeria, local in Morocco; appears to have decreased in numbers, but slight expansion in Morocco.

**Bibliography.** Adamian & Klem (1999), Barreau & Rocher (1992), Beaman & Madge (1998), Blagoslono (1968), Blume (1955, 1961, 1981, 1996), Blume *et al.* (1957), Chartier (1993), Chatfield (1970), Choffat (1995), Christen (1994), Cramp (1985), Cuisin (1999b), Dementiev *et al.* (1966), Diaz *et al.* (1996), Échécoar & Hùe (1964), Fry *et al.* (1988), Gluc & Boswell (1994), Gorman (1997a, 1999a), Groppali & Priano (1993), Hagemeijer & Blair (1997), Hågvar & Hågvar (1989), Hågvar *et al.* (1990), Handrinos & Akriotis (1997), Havelka & Ruge (1993), Heath & Evans (2000), Heath *et al.* (2000), Horstikotte (1973), Hùe & Échécoar (1970), Jourdain (1936), Kefler (1986), Knistauts & Lytkus (1981), Labitte (1953), Ledant *et al.* (1981), Löhrl (1977), Marchant *et al.* (1990), Melde (1994), Merikallio (1958), Mikusinski (2001), Mikusinski & Angelstam (1997, 1998), Mulhauser, Kaiser & Claude (2000), Mulhauser, Kaiser & Junod (2001), Nilsson *et al.* (1992), Osiek & Hustings (1994), Pechacek (1992, 1995, 1996), Pechacek & Kristin (1993), Purroy (1997), Radermacher (1970), Radford (1997), Rolstad *et al.* (2000), Ruedi (1983), Salomonsen (1947), Schandy (1981), Schmid (1993), Schneider (1979), Sermet (1983), Snow & Perrins (1998), Soler *et al.* (1982), Sotago (1954), Sparks (1995), Stenberg (1978), Stradi & Hudon (1998), Stradi *et al.* (1998), Südbek (1991), Svensson *et al.* (1999), Tobalske & Tobalske (1999), Tomec & Kilimann (1998).

## 194. Red-collared Woodpecker

### *Picus rabieri*

**French:** Pic de Rabier      **German:** Halsbandspecht      **Spanish:** Pito Vietnamita  
**Other common names:** Rabier's Woodpecker

**Taxonomy.** *Gecinus Rabieri* Oustalet, 1898, Tonkin. Monotypic.

**Distribution.** SC China (extreme S Yunnan), Laos and Vietnam (W & E Tonkin, N & C Annam); single report from Cambodia.

**Descriptive notes.** c. 30 cm. Male has whitish line above eye, olive-grey lores and ear-coverts, pale greenish-buff chin and throat often streaked white, sometimes some red feather tips; rest of head,

olive-grey, edged and tipped olive-green; underwing whitish, barred greyish-brown; undertail blackish, tinged green-yellow, especially on outer feathers, central feathers sometimes with narrow paler bars; fairly long bill broad-based, slightly chisel-tipped with curved culmen, overall blackish with paler base; iris reddish-brown or pinkish-brown; legs yellow-green or greenish-grey. Female has blackish forehead and crown, also less red in facial area, may also have less obvious red collar. Juvenile male resembles adult female, but duller above, greyer below, with orange-red on head and upper breast, crown mixed with black feathers. VOICE. Not described. Drums in fast irregular rolls of medium length.

**Habitat.** Broadleaved evergreen and semi-evergreen forest, also secondary growth; occurs also in tall mixed deciduous forest, and even in logged and disturbed forest with some large trees remaining. Lowlands to 700 m, very rarely to 1050 m.

**Food and Feeding.** Ants probably form main bulk of diet. Occurs singly, in pairs, or in family parties; regularly accompanies mixed-species flocks, e.g. with laughingthrushes (*Garrulax*) and other woodpeckers. Often forages low down on trees, and frequently on ground.

**Breeding.** May-Jun. No other details known.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Scarce to uncommon; locally more common (Laos). Occurs in Bach Ma and Cuc Phuong National Parks (Vietnam). First recorded in Cambodia in 2001. Has a very small known range, within which the continued degradation and destruction of lowland forest gives cause for concern. This species occurs in tall mixed deciduous forest in some places, and seems able to survive in logged and disturbed forest if some large trees remain; some evidence suggests that, locally, it may prefer the latter habitats. Even so, this is a very poorly known woodpecker, and research is needed to ascertain its precise habitat requirements, particularly in terms of nesting.

**Bibliography.** Andreev *et al.* (2001), Campey (1996), Cheng Tsohsin (1987), Collar & Andrew (1988), Collar *et al.* (1994), Delacour & Jabouille (1940), Duckworth (1996), Duckworth, Evans & Timmins (1993), Duckworth, Salter & Khounboline (1999), Duckworth, Timmins & Cozza (1993), Eames (1996), Evans & Timmins (1998), Inskipp *et al.* (1996), MacKinnon & Phillips (2000), Meyer de Schauensee (1984), Robson (1989, 2000), Robson *et al.* (1993a), Stattersfield & Capper (2000), Thewlis *et al.* (1998), Timmins *et al.* (1993), Tobias *et al.* (1998), Zhao Zhengjie (1995).

## 195. Black-headed Woodpecker

### *Picus erythropygius*

**French:** Pic à tête noire      **German:** Rotbürlspecht      **Spanish:** Pito Cabecinegro

**Taxonomy.** *Gecinus erythropygius* Elliot, 1865, Cochinchina. Races intergrade. Two subspecies recognized.

**Subspecies and Distribution.**

*P. e. nigrigenis* (Hume, 1874) - C & E Myanmar (S to N Tenasserim) and NW & W Thailand.

*P. e. erythropygius* (Elliott, 1865) - NE Thailand and Indochina.

**Descriptive notes.** 33 cm; 100-135 g. Male has black forehead, lores and cheeks to nape, red patch in centre of crown and sometimes down to eye; a few (both sexes and both races) have a thin whitish line from eye over ear-coverts; neck side, chin and throat to upper breast bright yellow, often tinged olive on upper breast; yellow-green mantle and back, bright red lower back and rump to central uppertail-coverts, tail-coverts otherwise olive-green with indistinct black shaft streaks; wing-coverts darker green, less tinged yellow; primary coverts and flight-feathers blackish, latter with 5 or 6 broad white bars; uppertail

blackish, central feathers edged green with obscure pale bars near base; lower breast brownish-white with faint chevrons, paler and whitish with heavier dark chevrons on flanks and belly; white undertail-coverts heavily barred dark brown; underwing whitish, blackish bars across flight-feathers; rather narrow pointed bill, slightly curved culmen, greyish-horn to yellow, darker tip; iris whitish to lemon-yellow, narrow orbital ring slate-grey; legs pale grey to grey-green. Female has crown entirely black. Juvenile less yellow above than adult, throat paler, upper breast buff, markings below more diffuse, male with some red feather tips on central crown. Race *nigrigenis* is very like nominate, but has blackish bill, male perhaps with more red in crown. VOICE. Distinctive undulating yelping laugh "ka-tek-a-tek-a-tek-a-tek" or "cha-cha-cha, cha-cha-cha", rapidly repeated, stress on first note in each series.

**Habitat.** Deciduous forest, especially dry dipterocarp, also pine (*Pinus*) forest. Recorded up to 1000 m, but generally commoner below 600 m.

**Food and Feeding.** Termites (Isoptera), also ants and other invertebrates. Usually in small, noisy groups of 2-6 birds, often associated with jays or treepies (Corvidae). Forages in canopy and in understorey; seems also to descend to lower levels, e.g. to stumps and the ground. Active and restless, constantly on the move through forest.

**Breeding.** Feb-Jun. Nest-hole in tree; clutch 3-4 eggs. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally scarce to uncommon; locally more common. Occurs in Doi Inthanon National Park (Thailand).

**Bibliography.** Baker (1919), Chazee (1944), Deignan (1945), Delacour & Jabouille (1940), Duckworth *et al.* (1999), Eames & Erickson (1996), Evans, G.H. (1905), Evans, T.D. & Timmins (1998), King & Rappole (2001), Lekagul & Round (1991), Riley (1938), Robson (2000), Smythies (1986), Thewlis *et al.* (1998).

196. Grey-faced Woodpecker

Picus canus

**French:** Pic cendré                      **German:** Grauspecht                      **Spanish:** Pito Cano  
**Other common names:** Grey-headed Woodpecker(!), Grey-headed Green Woodpecker, Ashy Woodpecker(!); Black-naped (Green) Woodpecker (*sobrinus*, *sanguineiceps*)

**Taxonomy.** *Picus canus* J. F. Gmelin, 1788, Norway. Has hybridized with *P. viridis* in C Europe. Races often divided into two main groups, the N “*canus* group” of two taxa and S & E “*guerini* group” of seven taxa, with two other isolated forms in the highlands of Peninsular Malaysia and Sumatra. Races intergrade in many areas. Several other races have been described throughout species’ vast range, but differ in only very minor, insignificant characters; thus, named races *perspicuus* (Bulgaria), *biedermanni* (Altai Mts), *zimmermanni* (NE China), *perpallidus* (Manchuria, Ussuriland, Korea), *setschuanus* (Sichuan) and *gyldenstolpei* (NE Indian Subcontinent) do not warrant separation. Eleven subspecies currently recognized.

**Subspecies and Distribution.**

- P. c. canus* J. F. Gmelin, 1788 - Europe (from S Scandinavia and France) E to W Siberia.
- P. c. jessoensis* Stejneger, 1886 - E Siberia to Sakhalin and N Japan (Hokkaido), S to NE China and Korea.
- P. c. sanguineiceps* Stuart Baker, 1926 - NE Pakistan, N India and extreme W Nepal.
- P. c. hessei* Gyldenstolpe, 1916 - Nepal E to Myanmar, extreme S China (S Yunnan) and most of Thailand to Vietnam.
- P. c. guerini* (Malherbe, 1849) - NC China S to C Sichuan.
- P. c. kogo* (Bianchi, 1906) - C China, from Qinghai E to Shanxi and S to Sichuan.
- P. c. sordidior* (Rippon, 1906) - SE Tibet E to W Sichuan, S to NE Myanmar and Yunnan.
- P. c. sobrinus* J. L. Peters, 1948 - NE Vietnam and SE China (Guangxi E to Fujian).
- P. c. tancolo* (Gould, 1863) - Taiwan and Hainan.
- P. c. robinsoni* (Ogilvie-Grant, 1906) - mountains of C Peninsular Malaysia (Gunung Tahan and Cameron Highlands).
- P. c. dedemi* (van Oort, 1911) - highlands of Sumatra.

**Descriptive notes.** 26-33 cm; 125-165 g (*canus*), 110-206 g (*jessoensis*), 143-165 g (*sanguineiceps*), 137 g (female *hessei*). Male has red upper forehead and forecrown (often yellowish at rear), crown usually with very fine black streaks, short pale line over eye, narrow black malar stripe often mottled grey at rear; rest of head and neck ash-grey, slightly tinged greenish when fresh, darker on nape and neck; chin and throat pale grey-white, tinged buff or olive; olive-green upperparts, yellowish or greenish-yellow on rump and uppertail-coverts, latter with olive-green feather bases, wing-coverts occasionally with slight bronze or yellowish tinge; primaries

greyish-black to brownish-black, small whitish spots on outer webs, sometimes also on some inner webs, secondaries greyish-black with dull olive-green outer webs, outer feathers often with paler spots; uppertail greenish-brown, obscure paler bars; pale grey below, lower flanks and belly with slight tinge of pale olive-green when fresh, occasionally obscure darker chevrons on lowermost underparts; underwing greyish, heavily barred; undertail blackish, tipped greenish-grey, a few obscure paler bars; fairly long bill slightly chisel-tipped, rather broad-based, culmen moderately curved, blackish-brown to grey-black, usually with olive tinge; iris pinkish to bluish-white, or deep carmine-red with admixed white; legs olive-grey to yellowish-olive. Female on average slightly smaller than male, proportionately shorter bill, head lacking red, has forehead and forecrown pale grey with narrow black shaft streaks, occasionally a few scattered red tips on forehead, black malar weaker and often incomplete. Juvenile duller than adult, greyer above with slight scaly appearance, rump more greenish, some indistinct bars on wing, malar more diffuse and mottled, inconspicuous darker barring below, eyes red-brown, male with small orange-red crown patch. Races highly variable, some highly distinctive: *jessoensis* is variable, generally slightly paler and greyer, less green, than nominate, in fresh plumage can be almost indistinguishable; *guerini* is greenish above and below, with black nape, female with pale-streaked black crown; *sobrinus* has golden tint above, is greener, less grey, below; *tancolo* is smaller than last, has deep green upperparts, very green underparts, greyer face; *kogo* is larger than previous, much paler green, female with black nape and pale-streaked black crown, a few greyish-green on head top; *sordidior* is same size as last, dark; *hessei* is even darker than previous, dark golden-green above, deeper green below, tail darker and less barred, crown and nape deep black, male with more extensive red on crown; *sanguineiceps* is largest race, plumage as previous but less golden or bronzy above, male with even more extensive red on crown; *robinsoni* is small, very dark green above and below, but paler throat, yellow-green rump, crown and nape black, male with red forecrown, female crown slightly streaked; *dedemi* is smallest and darkest, highly distinctive, deep brownish-red above, brighter red rump, unbarred blackish tail, reddish-brown with some admixed grey and greenish below, blackish undertail-coverts, crown and nape unstreaked black, male with small red forecrown patch, juveniles more blackish above and below. **VOICE.** Single “kik” calls; descending sequence of 5-20 clearly separated mournful “kiu” or “pew” notes, female’s series usually shorter, more raucous,

possibly also racial differences in number of syllables, series also softer and less descending in Himalayan birds than in C European ones; low “dyook dyook” series between partners at close distances; low to moderately loud “kyak kyak kyak” in agonistic situations; “wite-wite...” during body-swinging displays; “keek, kak kak kak kak” calls common outside breeding season. Drums regularly pre-breeding, rolls longer than those of *P. vittatus* but rhythm slightly slower, in Europe 19-40 strokes at rate of c. 20 per second.

**Habitat.** Great diversity of habitats occupied over wide range. Various types of temperate and moist subtropical forest, woodland, second growth with evergreen, deciduous and coniferous trees; trees can be dense, but some open ground required; occurs in parks, including larger ones in urban areas, but visits open country only when woodland nearby. In Europe, open country with many copses, in not over-dense forest, floodplain-forest, parks, orchards, gardens; associated mostly with deciduous trees, but locally in pine-oak (*Pinus-Quercus*) woodland, or more open coniferous montane forest with larch (*Larix*); broad overlap in habitat with *P. viridis*, but more in forest interior. Avoids pure coniferous *taiga* in C Siberia, preferring broadleaved forest. Open alder (*Alnus*) or oak forest in Nepal and N Myanmar, and open deciduous and coniferous country in Tibet and W China. Race *hessei* in Myanmar and Thailand prefers deciduous forest and drier and more open parts of teak forest, rather than evergreen; in highlands of S Annam (Vietnam), shows a liking for native pine forest. Other habitats in Asia include bamboo groves mixed with second growth. Considerable altitudinal range, from lowlands to mountains; lowlands and hills in Europe, to 1700 m, non-breeders to 2000 m; to 2200 m in Indian Subcontinent, but to 2600 m in Nepal (more common below 2000 m); to 2300 m in N Myanmar and China; c 900-1830 m in Peninsular Malaysia, and to 2000 m in Sumatra.

**Food and Feeding.** Appears to have more varied diet than that of *P. viridis*. Chiefly ants (*Myrmica*, *Lasius*), termites (Isoptera) and their brood, which often make up more than 90% of stomach contents; also other insects (e.g. Coleoptera larvae), and spiders; also nest contents of other birds. Fruits (e.g. apple, pear, cherries, camphor), berries, seeds (e.g. *Rhus*), nuts and acorns also consumed, and nectar taken. Regularly visits feeders. Usually solitary outside breeding season, otherwise in pairs or small family parties; in tropical areas (e.g. Thailand), will associate with mixed bird flocks of other terrestrial foragers. Regularly feeds on ground; probes into soil, pushing and digging with the bill, using the tongue to lick up prey. Funnel-shaped holes dug into ground, used repeatedly as sources of ants. Arboreal foraging with single pecks, some excavation in decaying wood at low levels, and intensive use of the tongue at crevices and sites of decayed wood. Also licks from sap wells, but seems not to ring trees itself. Simple anvils used occasionally. Moves on ground with heavy hops; otherwise, more lively and agile than *P. viridis*, flies even short distances within a tree.

**Breeding.** Lays from end Apr to early Jun. During courtship, landing with fluttering wingbeats associated with presence of partner and a nest-hole; occasional courtship feeding by male. Nest-hole excavated in 9-20 days or more, at 0.2-24 m, commonly between 1.5 m and 8 m, in dead wood or soft living wood, or in fungus-afflicted hard wood, most often in deciduous tree of variety of species; entrance hole a vertical oval c. 6 cm x 5.5 cm, cavity depth c. 28 cm. Clutch 4-10 eggs, clutch size varies geographically, generally 4-5 in Himalayas, 7-9 in C Europe; both sexes incubate, male during night, male also seems to incubate more than female during day, period 14-17 days; chicks fed by regurgitation, by both parents equally, helping by a second female known to have occurred; fledging period 23-27 days; young accompanied by parents for some time afterwards.

**Movements.** Essentially non-migratory. Some local post-breeding movements to more favourable, usually lower-lying, wintering grounds, e.g. riparian woodland, human habitations. Normally disperses farther than *P. viridis* in Europe; some nomadic winter movements occur among N Asian populations, also in connection with irregular movements of *Dendrocopos major* in Scandinavia.

**Status and Conservation.** Not globally threatened. Reasonably common, if rather local, throughout most of range. Locally common in Europe and much of Asia; widespread but generally uncommon in China; common or locally common in N Indian Subcontinent, but rare in Pakistan; fairly common to scarce in SE Asia, but rare to very rare in Peninsular Malaysia and Sumatra. Estimated population in European Russia c. 31,600 pairs; c. 94,000 pairs in rest of Europe, including 35,000 in Romania and 20,000 in Germany. Density in C Europe c. 0.1 pairs/km², locally up to 10 pairs/km². Has decreased in some areas, e.g. Romania, probably as a result of intensification of forestry methods. Few relevant data from other parts of range, but appears to be fairly stable.

## Genus *DINOPIUM* Rafinesque, 1814

### 197. Olive-backed Woodpecker

#### *Dinopium rafflesii*

**French:** Pic orillamme **German:** Olivrückenspecht **Spanish:** Pito Dorsioliva  
**Other common names:** Olive-backed Three-toed Woodpecker, Raffles's Woodpecker

**Taxonomy.** *Picus Rafflesii* Vigors and Horsfield, 1830, no locality = Sumatra. Individual variation considerable, and races poorly marked, differing only in size; described race *peninsulare* (Malacca) considered synonymous with nominate. Two subspecies recognized.

#### **Subspecies and Distribution.**

*D. r. rafflesii* (Vigors & Horsfield, 1830) - S Myanmar (S Tenneserim) and peninsular Thailand S to Sumatra, including Bangka.

*D. r. dultense* Delacour, 1946 - Borneo.

**Descriptive notes.** c. 26-28 cm; 87-119 g (*rafflesii*), 76-84 g (*dultense*). Male has red forehead, crown and crest, black and white stripes on side of head and down side of neck, buffy-yellow lores, cinnamon to yellowish or rusty malar area (sometimes red feather tips); chin and upper throat buffish-cinnamon, yellowish or rusty-yellow; hindneck and uppermost mantle black, rest of upperparts dark olive-green with bronzy or yellowish feather tips, rump and uppertail-coverts occasionally with orange tips (rarely, dull reddish), bronzy or yellowish olive-green wing-coverts; brownish-black flight-feathers, yellow-green outer

webs of secondaries, inner webs with white spots; uppertail black; olive to greyish-olive below, often with rusty staining, flanks usually with white spots, sometimes absent; underwing dark brownish, spotted white; fairly long bill chisel-tipped, culmen slightly curved, narrow across nostrils, grey to blackish; iris dark red-brown; legs blue-grey or grey, only 3 toes. Female has red on head replaced by black, forehead and crown often more olive, crest slightly smaller than male's. Juvenile duller, greyer, male with crown blackish or dark olive, red only on crest or also a few scattered spots on forehead, females as adult but crown more olive. Race *dultense* is smaller than nominate. **Voice.** Single "chak" note; also rapid series of loud notes in 2 versions, slow "chakchakchak-chak", 6-34 notes, varies in rate and pitch, sometimes single notes appended, given when pair-members interact, and faster, more regular, with 10-50 notes, probably as territorial call; low "ch-wee, ch-wee, ch-wee" calls during encounters and sometimes associated with head-swinging; soft, even trilling "ti-i-i-i-i", and squeaky "tiritit" also described. Not known to drum, but incubating birds tap in soft regular bursts of 10-12 strokes.

**Habitat.** Dense, wet evergreen forest, including swamp-forest, mangroves; avoids secondary growth and clearings. Mainly lowlands and hills, to 1200 m; locally to 1600 m in Borneo.

**Food and Feeding.** Ants, termites (Isoptera), and especially ant pupae. Singly and in pairs. Forages at low and middle heights, below 10 m, on fallen logs, at bases of trees and saplings, and to tops of lower saplings and snags; also on branches of lower crown. Rarely, ventures outside forest to visit dead stumps. Main technique is gleaning; pecks occasionally, more frequently than *D. javanense*. Moves slowly and continuously, pausing only briefly.

**Breeding.** Mar-May; apparently Oct in Borneo. Displays include crest-raising, bowing movements, head-swinging; courtship feeding by male. Nest excavated by both sexes, at 4-5-9 m up in tree, even in live wood. Clutch size not recorded; both sexes incubate. No other information.

#### **Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Scarce to uncommon throughout its range; perhaps somewhat commoner in parts of Borneo; extinct in Singapore. Occurs in several protected areas, e.g. Kaeng Krachan National Park (Thailand) and Gunung Mulu National Park, Batu Punggul Forest Reserve, and Danum Valley Conservation Area (Borneo). Within this species' range, huge areas of lowland forest have already been destroyed; although it appears to remain in reasonable numbers in the higher parts, additional habitat loss could easily pose a major threat.

**Bibliography.** Andreev *et al.* (2001), Andrew (1992), Baker (1919), van Balen (1999), Bucknill & Chasen (1990), Castelletta *et al.* (2000), Danielsen & Heegaard (1995), Delacour (1951a), Duckworth & Kelsh (1988), Duckworth *et al.* (1997), Dupond (1942), Inskipp *et al.* (1996), Jepson & Brinkman (1993), Jeyarajasingam & Pearson (1999), Lekagul & Round (1991), MacKinnon & Philipps (1993), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Riley (1938), Robinson & Kloss (1924a), Robson (2000), Short (1973d), Smythies (1986, 1999), Stattersfield & Capper (2000), Vowles & Vowles (1997), Wells (1985, 1999), Wilkinson, Dutson & Sheldon (1991), Wilkinson, Dutson, Sheldon, Darjono & Noor (1991), Wong (1985).

### 198. Himalayan Flameback

#### *Dinopium shorii*

**French:** Pie de Shore **German:** Himalaya-Feuerrückenspecht **Spanish:** Pito de Shore  
**Other common names:** Himalayan Goldenback, Himalayan/Three-toed Golden-backed Woodpecker

**Taxonomy.** *Picus Shorii* Vigors, 1832, Himalayas.

Forms a superspecies with *D. javanense*. Races weakly differentiated. Two subspecies recognized.

#### **Subspecies and Distribution.**

*D. s. shorii* (Vigors, 1832) - N India (Haryana) E through lowlands and S foothills of Himalayas to Nagaland and N Bangladesh; possibly still in peninsular hills (Eastern Ghats).

*D. s. anguste* Ripley, 1950 - W Myanmar.

**Descriptive notes.** 30-32 cm; 101 g. Male has yellowish-red forehead, redder on crown and crest, narrowly bordered black; broad black and white bands on side of head and neck, pale reddish malar stripe outlined in black, becoming all black at rear and continuing down to side of breast; whitish

chin, thin buff-brown central line broadening through centre of throat and expanding over upper breast, where bordered with black spots; hindneck and upper mantle black; lower mantle, scapulars and upper back olive-green with yellow or golden feather tips, strongly red on edges and tips; lower back to rump bright red, uppertail-coverts blackish olive-brown with some red tips; wing-coverts with a hint of red; flight-feathers blackish-brown, yellow-olive outer webs of secondaries, inner webs spotted white; uppertail black; white below, feathers with brownish-black edges and black tips creating sealy pattern; underwing brown,

spotted white; undertail brownish-black, outer feathers tinged yellow-olive; longish bill almost pointed, curved culmen, narrow across nostrils, blackish; iris red to brownish, possibly sometimes gold or crimson; legs green-grey or brownish-green, 3 toes. Female has blackish crown and crest with narrow white streaks, pale malar with black outline. Juvenile browner than adult, markings below more obscure, male with forehead and crown brownish-buff and streaked paler, red only on crest, female with brown crown and crest with broad pale streaks. Race *anguste* has bill, wing and tail a little smaller than nominate, possible tendency for slightly less red on back, female has crown streaks much finer than nominate and hindcrown almost unstreaked. **Voice.** Rapid tinny "klak-klak-klak-klak", slower and not so loud as that of *Chrysocolaptes lucidus*.

**Habitat.** Mature deciduous and semi-evergreen forest; in deciduous forest in Nepal, preferring primary lowland forest with *Ficus* and *Bombax*. Lowlands and foothills, up to c. 700 m, locally to 1220 m; below 300 m in Nepal.

**Food and Feeding.** Poorly known. No details of diet. Associates with mixed-species flocks; also with *Chrysocolaptes lucidus* where the two occur together.

**Breeding.** Mar-May; nest-hole excavated in tree; clutch 2-3 eggs. No other information.

#### **Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common locally; rare in Bangladesh; uncommon in Myanmar. Occurs in several protected areas, e.g. Corbett National Park (India) and Chitwan National Park (Nepal). Very poorly known species; requires field research. Could be seriously affected by deforestation.

**Bibliography.** Abdulali & Hussain (1973), Ali & Ripley (1983), Ali *et al.* (1996), Barua & Sharma (1999), Biswas (1961a), Choudhury (2001), Delacour (1951a), Grimmer *et al.* (1998, 2000), Harvey (1990), Inskipp, C. & Inskipp (1991, 1993), Inskipp, C. *et al.* (1999), Inskipp, T. *et al.* (1996), Javed & Rahmani (1998), Kazmierczak (2000), MacKinnon & Philipps (2000), Ripley (1950a, 1982), Robson (2000), Shrestha (2000), Smythies (1986), Waite (1938).

### 199. Common Flameback

#### *Dinopium javanense*

**French:** Pic à dos rouge **German:** Feuerrückenspecht **Spanish:** Pito Culirrojo  
**Other common names:** Common Golden-back, Common Golden-backed Woodpecker, Golden-backed Three-toed Woodpecker; Indian Flameback (*malabaricum*)

**Taxonomy.** *Picus javanensis* Ljungh, 1797, Java.

Forms a superspecies with *D. shorii*. Proposed race *borneonense* (Borneo except NE) considered inseparable from nominate. Six subspecies recognized.

#### **Subspecies and Distribution.**

*D. j. malabaricum* Whistler & Kinnear, 1934 - W India.

*D. j. intermedium* (Blyth, 1845) - Bangladesh and Assam to C & E Myanmar, SC China (SW Yunnan) and N Vietnam, and S to Thailand (except peninsular) and Cochinchina.

*D. j. everetti* (Tweeddale, 1878) - W & C Philippines (Balabac, Palawan and Calamian Is).

*D. j. javanense* (Ljungh, 1797) - peninsular Thailand S to Sumatra, including Riau Archipelago, W Java and Borneo.

*D. j. raveni* Riley, 1927 - NE Borneo and offshore islets.

*D. j. exsul* (Hartert, 1901) - E Java and Bali.

**Descriptive notes.** 28-30 cm; 67-90 g (*javanense*), 85-98 g (*everetti*), 79-100 g (*intermedium*). Male has brownish-red forehead and upper lores, red crown and crest, crown narrowly edged black; white supercilium from above eye to nape side, black stripe from eye to hindneck, broad white cheekstripe from lores continuing down side of neck to side of breast; thin black moustachial line, broader at rear, then continuing down to upper breast; buffish chin and throat, central line of small black spots from bill base generally somewhat broader and more numerous on lower throat; hindneck and upper mantle black; rest of upperparts mostly

olive with strong golden suffusion, yellow feather tips, sometimes also hint of orange or red, lower back and rump bright red; uppertail-coverts blackish-brown, occasionally tinged olive; outer webs of secondaries and tertials olive-yellow, rest of flight-feathers blackish-brown, white spots on inner webs; uppertail black; white below, feathers irregularly edged and tipped black, markings heaviest on breast, less prominent and more bar-like on lower underparts; underwing brown, spotted white; undertail brownish-black, outer feathers tinged yellowish; shortish bill pointed, curved on culmen, narrow across nostrils, blackish to dark grey-brown, paler base; iris red-brown or brown, orbital skin black; legs grey or brown, usually tinged greenish, 3 toes. Female has crown and crest black with white streaks. Juvenile very like adult, but breast more blackish-brown with white spots, lower underparts more obscurely barred, eyes greyer, male with black forehead and crown, red crest, female with pale crown streaks more spot-like. Other races differ little from nominate, only one being distinctive: *intermedium* is very like nominate but bigger, with whiter throat; *malabaricum* is on average slightly smaller than last, has back and wings less golden-yellow, more olive; *exsul* has underparts strongly but irregularly barred, female with narrow orange to red napeband; *raveni* is

slightly more buff and less black below, throat more broadly spotted, female tending to have crown streaks very narrow; *everetti* is distinctive, has pale reddish or buff-brown colour from throat to upper breast, throat spots more extensive, more barred pattern below, males with red of crown extending to side of head, dark eyestripe broader, red tips in malar, female with red on nape and crest, very small streaks on crown or none. Voice. Variable series of notes, "kowp-owp-owp", in flight; single or double "kow" when perched; "wicka"-like calls with display during encounters; rattle a harsh prolonged "churrrrrrr", or "ka-di-di-di-di-di", faster than that of *D. rafflesii*. Drums more softly than *Chrysocolaptes lucidus*.

**Habitat.** Moist secondary and open forest, open deciduous woodland, scrub, and mangroves; also in teak forest and, at higher elevations, in pine (*Pinus*) forest. Favours penang and coconut groves, cultivation, gardens, parkland, and golf courses. Generally found in lowlands, but up to 1000 m in Greater Sundas, to 1530 m in Myanmar, and to 1700 m in India.

**Food and Feeding.** Ants, insect larvae; also small scorpions (Scorpiones), cockroaches (Blattodea), other insects. In pairs, or in mixed-species flocks. Forages at all levels, with preference for lower parts of trees, but also inspects crown branches and all other parts of trees and palms. Main techniques are gleaning, sideways reaching, and probing; occasionally pecks, as when removing loose bark. Climbs quickly and erratically, with occasional brief pauses. Observed to hawk flying insects. Sometimes moves long distances between foraging sites.

**Breeding.** Jan-Jun, mostly Feb-Apr, in India; Jan-Oct in SE Asia, mostly Jun in Thailand, to Jul in Peninsular Malaysia; Apr-Jul and Nov-Dec in Borneo; Mar-Apr in Philippines. Displays include crest-raising, bowing movements, head-swinging; male courtship-feeds female. Nest-hole excavated at 1-4-10 m, mostly below 5 m, in tree or stump, often usually in fruit tree or coconut palm, in open area. Clutch 2 or 3 eggs; no information on incubation and fledging periods. Maximum recorded longevity 10 years, 6 months.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Locally fairly common in India; local in Bangladesh; uncommon to common in SE Asia; uncommon in Philippines. Occurs in many protected areas in all parts of its range, e.g. Baluran, Mudumalai, Periyar and Kaziranga National Parks (India), Khao Yai National Park (Thailand), Nam Bai Cat Tien National Park (Vietnam), Bako National Park (Malaysia), Sungei Buloh Nature Reserve (Singapore), Way Kambas National Park (Sumatra) and St Paul's Subterranean River National Park (Palawan, Philippines). Could be adversely affected by habitat destruction, but preference for more open woodland is an advantage; accepts human-altered landscapes.

**Bibliography.** Ali (1996), Ali & Ripley (1983), Andrew (1992), Baker (1919), van Balen (1999), Bangs & Van Tyne (1931), Betts (1934), Bucknill & Chasen (1990), Champion-Jones (1938), Chasen (1935), Deignan (1945), Delacour (1951a), Dickinson *et al.* (1991), Edgar (1933), Grimmett *et al.* (1998), Hails & Jarvis (1987), Harrison (1958), Harvey (1990), Inskipp *et al.* (1996), Jayarajasingam & Pearson (1999), King & Rappole (2001), Lainer (1999), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Philipps (1993, 2000), Madoc (1976), van Marle & Voous (1988), McClure (1998), Medway & Wells (1976), Mees (1996), Meyer de Schauensee & Ripley (1940), Noske (1991), Parrott & Andrew (1996), duPont (1971), Ripley (1938), Ripley (1982), Robinson & Kloss (1924b), Robson (2000), Sargeant (1997), Short (1973d), Smythies (1986, 1999), Spittle (1949, 1952), Stepanyan (1995), Vowles & Vowles (1997), Wells (1999), Zacharias & Gaston (1999), Zhao Zhengjie (1995).

## 200. Black-rumped Flameback

### *Dinopium benghalense*

**French:** Pic du Bengale **German:** Orangespecht **Spanish:** Pito Bengali  
**Other common names:** Lesser Flameback/Goldenback, Lesser/Black-rumped Golden-backed Woodpecker; Ceylon Golden-backed Woodpecker (*psarodes*)

**Taxonomy.** *Picus benghalensis* Linnaeus, 1758, Bengal.

S Sri Lankan race sometimes referred to as *erithronothos* (or, erroneously, as *erithronothos*), but *psarodes* has priority. Clinal decrease in size and variation in colour from N to S, and considerable individual variation, together with intergrading of populations, all combine to make racial delimitation difficult; indeed, W Indian birds sometimes separated as race *tehinnae* and those in N Sri Lanka as *jaffnense*, but both probably more appropriately included in *puncticolle*. Four subspecies currently recognized.

**Subspecies and Distribution.**

- D. b. dilutum* (Blyth, 1849) - Pakistan.
- D. b. benghalense* (Linnaeus, 1758) - NW & N India E to Assam and SW Myanmar.
- D. b. puncticolle* (Malherbe, 1845) - C India S to N Sri Lanka.
- D. b. psarodes* (A. A. H. Lichtenstein, 1793) - Sri Lanka (except N).

**Descriptive notes.** 26-29 cm; 86-133 g. Male has black forehead and crown with red feather tips, red crest; white supercilium, white-streaked black band from eye through ear-coverts, white cheekband meeting supercilium at rear, continuing down side of neck to side of upper breast; chin and throat black, broadly streaked white; hindneck and upper mantle black; lower mantle, scapulars and upper back golden-yellow, lower back to uppertail-coverts black; wing-coverts golden-olive, outer medians and most of lesser black with white subterminal spots, inner greater often with white central streak; flight-feathers brownish-black, outer webs of

tertials and secondaries golden-olive, primaries and inner webs of secondaries and tertials with well-spaced white spots; uppertail black; white to buffish-white below, feathers broadly edged and tipped black on breast, more narrowly on lower underparts, sometimes more bar-like on belly and undertail-coverts; underwing brown, coverts white with black barring; in worn plumage, forehead and crown mostly black, often olive feather bases visible on back; longish bill almost pointed, culmen curved, fairly narrow across nostrils, blackish; iris red-brown to crimson, orbital skin green to grey; legs grey-green. Female has forehead and forecrown black with small white spots. Juvenile duller than adult, black areas browner, underparts greyer and more obscurely marked, male with narrower red tips and sometimes white spots on crown, female with few or no crown spots. Race *dilutum* is generally paler golden-yellow above, whiter below; *puncticolle* has back and wings more orange-yellow, throat spotted rather than streaked, lower underparts more creamy, variable, sometimes olive wash on rump and wing-coverts, wing-covert spots smaller or lacking (especially in W & SW India); *psarodes* is distinctive, has black and wings deep crimson-red, often red tips on rump and tail-coverts, also more black on crown, black eye-stripe extending to hindneck, often more black on throat and underparts, proportionately longer tail. Voice. Single strident "kiek"; repeated "kyi-kyi-kyi", from perch or in flight; high-pitched squeaks by excited birds in encounters. Drums in weak bouts lasting 2-3 seconds.

**Habitat.** All types of moist to dry woodland, mostly deciduous; open woodland and light forest, groves around villages, old wooded gardens, tree plantations along roads and canals, open country with trees. Found in *Borassus* palms and coconut (*Cocos nucifera*) plantations, as well as rubber plantations in S India. Avoids heavy forest and arid regions. Lowlands, to 1200 m; in coastal areas in N Sri Lanka; locally to 1700 m in India.

**Food and Feeding.** Chiefly ants, e.g. *Camponotus* and *Meranoplus*, and including larvae and pupae of the fierce red ant *Oecophylla smaragdina*. Spiders, caterpillars, also weevils (Curculionidae) and other beetles, taken occasionally. Fruits (e.g. mango) and nectar not uncommon constituents of the diet. Often in pairs and with mixed-species flocks. Forages at all levels in trees; clings to underside of horizontal branches, moves backwards occasionally. Breaks into leaf-nests of *Oecophylla smaragdina*; also descends to the ground to feed at ant nests.

**Breeding.** Mainly Mar-Apr, in S India also in Jul-Aug, and in Dec-Sept, depending on conditions, in Sri Lanka; sometimes 2 broods in a season in S. Crest-raising by male, which also observed to feed insects to female. Nest-hole excavated by both sexes, often low, down to 1-5 m, but sometimes to 15 m, in tree with soft or hard wood (e.g. acacia, tamarisk, mango), or in palm; entrance hole c. 8 cm in diameter. Clutch 2 or 3 eggs; incubation by both parents, period 17-19 days; both also feed chicks, by regurgitation; fledging period c. 3 weeks.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common to locally common throughout range; one of the commonest and most widespread woodpeckers in Indian Subcontinent. Occurs in numerous protected areas, e.g. Chitwan National Park (Nepal), Corbett, Bharatpur, Ranthambore, Mudumalai, Periyar and Kaziranga National Parks (India) and Bellanwila-Attidiya Sanctuary (Sri Lanka). Seems unlikely to be at risk in the immediate future.

**Bibliography.** Alagar (1992), Ali (1996), Ali & Ripley (1983), Balasubramanian (1992), Betts (1934), Chakravarthy (1988), Champion-Jones (1938), Gokula & Vijayan (1997), Grimmett *et al.* (1998, 2000), Harrison (1999), Harvey (1990), Henry (1998), Himmatsinhji (1980), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Javed & Rahmani (1998), Jha (1999), Jones *et al.* (1998), Kalsi (1998), Kazmierczak (2000), Khacher (1989), Lainer (1999), Lamsfuss (1998), Mason & Lefroy (1912), Mohan (1997), Mukherjee (1995), Neelakantan (1962), Phillips (1978), Rajan (1992), Ripley (1982), Roberts (1991), Robson (2000), Santharam (1998a, 1998c), Shrestha (2000), Smythies (1986), Van Tyne & Koelz (1936), Vijayaraghavan (1957).

## Genus *CHRYSOCOLAPTES* Blyth, 1843

## 201. Greater Flameback

### *Chrysocolaptes lucidus*

**French:** Pic sultan **German:** Sultanspecht **Spanish:** Pito Sultán  
**Other common names:** Greater Goldenback, Greater/Large Golden-backed Woodpecker; Crimson-backed Woodpecker (*gutacristatus*)

**Taxonomy.** *Picus lucidus* Scopoli, 1786, Mindanao, Philippines.

Exhibits considerable individual variation and, in particular, extreme geographical variation in plumage, especially in E of range; appreciable size variation also exists, being largest in N & W. Race *gutacristatus* has sometimes been treated as separate species, as also has *strictus*. Further research may reveal that some of the more distinctive taxa, especially those isolated on islands, have evolved into full species, but present knowledge insufficient to enable accurate assessment; DNA analysis and detailed study of vocalizations and ecology required. Proposed races *sultaneus* (N India, Nepal), *grandis* (Polillo, in Philippines) and *maculiceps* (Basilan, in Philippines) considered too poorly differentiated to warrant recognition. Thirteen subspecies recognized.

**Subspecies and Distribution.**

- C. l. socialis* Koelz, 1939 - W coast of India.
- C. l. gutacristatus* (Tickell, 1833) - NW India and Nepal E to S China (Yunnan) and S to Thailand and Indochina.
- C. l. stricklandi* (E. L. Layard, 1854) - Sri Lanka.
- C. l. chersoneus* Kloss, 1918 - Peninsular Malaysia S to Sumatra and W Java.
- C. l. andrewsi* Amadon, 1943 - NE Borneo (from around Sandakan to Sebatik I).
- C. l. strictus* (Horsfield, 1821) - E Java.
- C. l. kangeanensis* Hoogerwerf, 1963 - coastal E Java, Bali and Kangean Is.
- C. l. haematribon* (Wagler, 1827) - N Philippines (Luzon, Polillo, Marinduque and Catanduanes).
- C. l. erythrocephalus* Sharpe, 1877 - Balabac, Palawan and Calamian Group.
- C. l. xanthocephalus* Walden & E. L. Layard, 1872 - Ticao, Masbate, Panay, Guimaras and Negros.
- C. l. rufopunctatus* Hargitt, 1889 - Samar, Biliran, Leyte, Calicoan, Bohol and Panaon.
- C. l. lucidus* (Scopoli, 1786) - Basilan and W Mindanao (Zamboanga Peninsula).
- C. l. montanus* Ogilvie-Grant, 1905 - Mindanao (except W) and Samal.

**Descriptive notes.** c. 28-34 cm; 150-233 g (*gutacristatus*), 110-145 g (*haematribon*), 125-164 g (*rufopunctatus*), 127 g (*lucidus*). Male has deep crimson forehead, crown and crest, reddish-buff face, neck and upper breast with broad black feather edges; upperparts and wings deep crimson-red, rump bright red; flight-feathers blackish, outer webs of secondaries olive-gold to reddish, all with white spots on inner webs; uppertail black; underparts light golden with broad black feather edges; long bill slightly chisel-tipped, straight, broad across nostrils, blackish; iris bright red, orbital ring purplish; legs green-brown. Female has crown and crest dark olive-brown to reddish-black with dark golden spots. Juvenile is duller than adult, more olive-tinged, more obscurely marked below, has brown eyes, male with less red in crest.

Races differ considerably in plumage, those from India to Indonesia mostly having golden-green to olive or bronzy back and wings, black and white bands on face and neck, white underparts with black scalloping, male with bright red crown and crest, those in Philippines highly variable, iris red in Philippine races, pale in all other races; *gutacristatus* is largest race, has forehead, crown and crest red, broad black and white bands on face, golden-olive or golden-green back and wings, bright crimson-red rump, white to buff-white underparts with feathers edged and tipped black, black strongest on throat and breast, pale creamy eyes, female has similar head pattern to male, but crest black

with white spotting; *socialis* is slightly smaller than previous, back and wings more olive, less golden, red of rump extending farther up back; *stricklandi* is smaller than last, back and wing-coverts entirely dark red, more black on head and neck side, much narrower white supercilium, bill and eyes very pale; *chersonesus* has olive back and wings, broad black markings below, broad white supercilium; *andrewsi* is larger than previous, dark markings below distinctly browner, less black, flanks more barred; *strictus* is small, has back and wings yellow-green, red of rump duller with hint of spots or bars, pale areas of head and breast buffish, female with crown and crest golden to orange-gold; *kangeanensis* is smaller than last, with redder rump, reduced black facial markings, dark markings below narrower and browner, female crown and crest golden-yellow; *erythrocephalus* has back and wings golden-green with traces of red (all other Philippine races red-backed), red of rump extending well up back, neck with fairly narrow black and white stripes, pale bill and legs, male with entire head and crest red, black spot on ear-coverts, thin dark malar, female has head darker with pale golden crown spots; *montanus* is like nominate but slightly smaller, with more gold or yellow in upperparts, dark markings below browner, less black; *rufopunctatus* has back and wings dark red, reddish-buff face, belly strongly patterned dark, male usually with black-bordered pale red malar, female crown and crest dark brown with reddish-buff spots; *xanthocephalus* is small, highly distinctive, with back and wings dark red, crown and crest red, head, neck and entire underparts golden-yellow, dark markings restricted to neck and upper breast, usually thin blackish malar, bill and legs pale, female with entire head yellow, often tinged orange on crest; *haematribon* has dark red back and wings often tinged olive, belly buffish with grey-brown barring obscure, male with much black on face and neck, female head dark with prominent white spots from forehead to crest. VOICE. Single "kik" calls occasionally; more often short or longer series of highly variable "kowk-kowk", "ke-dew-kow" or single "kow" notes, especially in flight; rapid insect-like series, monotonous or varying in speed and pitch, e.g. "di-di-di-di-di-di", "tibittititititit" or "kikikikikikit", sometimes rather long, both on the wing and when perched, possibly some variation at subspecific level: "t-wuit-wuit" series during close encounters. Drums loudly, rolls are c. 2 seconds long, accelerating and weakening.

**Habitat.** Open deciduous and evergreen forest, secondary forest, edge of primary forest, riparian woodland in open country, old plantations. Mangroves in Peninsular Malaysia, Sumatra and Borneo. More humid areas preferred. Mature lowland forest with big trees and mixed *Bombax-Ficus* are main habitats in Nepal. In Philippines, found in primary forest, mature secondary forest, lighter secondary forest with dense understorey, dense riparian vegetation, also near cultivations and close to human settlements. Found at all elevations, to over 2100 m, in Sri Lanka; to 920 m in Nepal; in India, to 1600 m in N and to 1800 m in S; below 1200 m in SE Asia; from lowlands to 1500 m in Philippines.

**Food and Feeding.** Large caterpillars, larvae of wood-boring beetles, pupae, ants and other insects; also takes nectar. In pairs and in family parties; associates also with other woodpecker species, e.g. *Dryocopus javensis*. Forages almost exclusively on big trees and snags, including somewhat isolated ones in the open; sometimes descends to ground. Prefers trunks and larger branches. Pecking and hammering to excavate wood are commonest foraging techniques; large pieces of bark removed with powerful lateral blows, and probing for prey follows. Pecking and probing also used to uncover subsurface prey among epiphytes. Movements rapid; tree searched from base of trunk to canopy, though much time is spent at a single site when substrate excavated. Gleans rarely; occasional flycatching, e.g. for swarming termites (Isoptera). Will move long distances, including over open areas, from one tree to the next.

**Breeding.** Mar-May in N India, Dec-Mar in S; in Sri Lanka Aug-Apr, mainly Dec-Jan; from Dec in SE Asia; Jul-Nov in Greater Sundas, and Feb-Aug in Philippines. Nest-hole excavated by both sexes, work sometimes taking 4 weeks, at 2-20 m in tree of variety of types, often in soft live wood (although heart of trunk may be rotten); entrance a vertical oval in shape. Clutch 2 eggs in S areas, 4-5 in N; incubation by both parents, period 14-15 days; chicks fed by both parents, which carry food in tip of the bill, fledging period 24-26 days; young stay with parents for some weeks, possibly until start of next breeding season.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common, or at least locally common, throughout much of range; local in Peninsular Malaysia; rare in China; only few recent records from Java (in E) and Bali; fairly common in Philippines. Occurs in numerous protected areas in many countries. Not likely to become threatened overall, but could be at risk to some extent in some areas; continued habitat destruction in Greater Sundas and Philippines, for example, may eventually result in populations falling to levels at which survival becomes difficult. Taxonomic revision urgently required, particularly as it may call for recognition of several species within this complex, and some of these could well prove to be threatened.

**Bibliography.** Ali & Ripley (1983), Ali *et al.* (1996), Andrew (1992), Bangs & Van Tyne (1931), Betts (1934), Biswas (1961a), Bucknill & Chasen (1990), Chasen (1931, 1935), Danielsen *et al.* (1994), Deignan (1945), Delacour & Mayr (1946), Dickinson *et al.* (1991), Eames & Robson (1992), Evans *et al.* (1993), Frith & Frith (1978), Gilliard (1950), Gonzales (1983), Goodman & Gonzales (1990), Grimmett *et al.* (1998), Hachisuka

## 202. White-naped Woodpecker

### *Chrysocolaptes festivus*

**French:** Pic de Goa **German:** Goldschulterspecht **Spanish:** Pito Dorsiblanco  
**Other common names:** Black-rumped Woodpecker, Black-backed Woodpecker(!), Black-backed Yellow Woodpecker

**Taxonomy.** *Picus festivus* Boddaert, 1783, Goa, India.

Two subspecies recognized.

**Subspecies and Distribution.**

*C. f. festivus* (Boddaert, 1783) - SW Nepal and most of India (except E coast).

*C. f. tantus* Ripley, 1946 - N & S Sri Lanka.

**Descriptive notes.** c. 29 cm; 213 g. Male has white forehead spotted brown, red crown and crest narrowly bordered black, broad white supercilium back to side of nape and sometimes meeting white of hindneck, broad black band through ear-coverts and down side of neck to side of upper breast, bordered below by white stripe from lores; white malar area enclosed by 2 thin black lines; white chin and throat with narrow black central line; white hindneck and mantle, black scapulars and back to uppertail-coverts, rump occasionally showing some yellowish feather edges; wing-coverts mostly olive-green with golden-yellow suffusion,

golden tips and edges (occasionally tinged red); flight-feathers brownish-black, olive-yellow outer webs of secondaries and tertiaries, white spots on (usually) both webs; uppertail black; underparts white, black throatstripe breaking into streaks on foreneck and breast, narrower streaks on lower underparts; undertail-coverts often more barred; underwing dark grey, spotted white; very long bill almost straight, chisel-tipped, broad across nostrils, blackish; iris red to orange; legs green-grey. Female has crown and crest yellow, usually some brown at front and side. Juvenile as adult but duller, black areas browner, can show some red in rump, eyes brown, male with yellow crown with orange-red tips, female crown as adult but some orange in nape area. Race *tantus* is slightly smaller than nominate, has blackish forehead, broader black gular stripe, broader black streaks below. VOICE. Laughing rattle, "kwirri-rr-rr-rr-rr", like corresponding call of *C. lucidus* but weaker. Drums.

**Habitat.** Open deciduous woodland and scrub; also cultivations with scattered trees. Plantations around villages in the dry zone in Sri Lanka. Lowlands and foothills, to c. 1000 m.

**Food and Feeding.** Ants, and larvae of wood-boring insects; also seeds, seemingly indicating ingestion of fruits. Feeds singly or in pairs; sometimes family parties. Forages in lower strata, on tree trunks; occasionally on ground, especially at bare patches. Pecking and hammering seem to be major feeding techniques.

**Breeding.** Season varies regionally, generally Nov-Mar; in Sri Lanka, also in Aug-Sept. A new nest-hole excavated each year, by both sexes, at 2-7 m in tree or palm stump; entrance pear-shaped. Clutch usually only 1 egg, rarely 2 or 3; incubation by both parents, both also feeding chicks; incubation and fledging periods not documented; young accompanied by parents for a long time after fledging.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon in Nepal; widespread and locally fairly common in India; scarce and local in Sri Lanka. Occurs in several protected areas, e.g. Corbett, Ranthambore, Rajiv Gandhi (Nagarhole) and Mudumalai National Parks (India) and Yala National Park (Sri Lanka).

**Bibliography.** Abdulali (1985), Ali (1996), Ali & Ripley (1983), Betts (1934), Daniels, R.J.R. (1997), Fleming & Traylor (1968), Gokula & Vijayan (1997), Grimmett *et al.* (1998, 2000), Harrison (1999), Henry (1998), Hoffmann (1998), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Kazmierczak (2000), Kirkpatrick (1960), Lamsfuss (1998), Neelakantan (1958), Phillips (1978), Ripley (1982), Shrestha (2000), Tirimanne (1978).

Genus *GECINULUS* Blyth, 1845

203. Pale-headed Woodpecker

*Gecinulus grantia*

**French:** Pic grantia **German:** Blassscheitel-Bambusspecht **Spanish:** Pito del Bambú Norteño  
**Other common names:** Bamboo Woodpecker (when lumped with *G. viridis*)

**Taxonomy.** *Picus (Chrysnotus) Grantia* McClelland, 1840, Assam. Forms a superspecies with *G. viridis*, and the two are sometimes treated as conspecific. Three subspecies recognized.  
**Subspecies and Distribution.**  
*G. g. grantia* (McClelland, 1840) - E Nepal E to N, C & S Myanmar and S China (W Yunnan).  
*G. g. indochinensis* Delacour, 1927 - SW Yunnan, NW Thailand, Laos and Vietnam.  
*G. g. viridanus* Slater, 1897 - SE China (N Guangdong, Fujian).

**Descriptive notes.** 25-27 cm; 68-85 g. Male has greenish-yellow crown to nape and crest, central patch of red-tipped pinkish feathers reaching to upper nape; rest of head and neck buff-green to pale olive-brown, tinged yellow, darker and more olive on chin and throat; upper mantle dark olive, rest of upperparts, and secondaries and tertiaries, dull brownish-crimson; brown primaries narrowly edged dull red on outer webs, with broad buff bars; uppertail blackish-brown, edged reddish, variable broad buff barring; dark olive or brownish-olive below, sometimes browner in lower region; underwing brownish with faint barring, coverts mottled grey and whitish; undertail as above, with dull yellow-green cast; fairly long bill chisel-tipped, culmen slightly curved, broad across nostrils, pale horn-yellow to whitish or pale ivory, grey or greenish base; iris red or reddish-brown; legs olive-green, 3 toes. Female has forehead to nape yellow-green, yellower at rear. Juvenile resembles female but darker, upperparts dark brown, underparts very dark brown to grey-brown. Races differ mainly in colour of upperparts and crown pattern: *indochinensis* is duller red above than nominate, greyer and less yellow on side of head, more sooty-brown, less olive, below, has dull buffish wingbars continuing over secondaries, male with crown patch more pinkish, less crimson; *viridanus* is bigger, with proportionately longer tail, shorter bill, even less red than previous, more olive above and grey-brown below, male's crown patch dull pink. Voice. Nasal "chaik-chaik-chaik-chaik" or "kwéek kwék-kwék", 4-5 times in succession, accelerating and becoming lower towards end; loud castanet-like rattles, "kereki kereki kereki kereki", when agitated; also series of "kwee-kwee" notes. Drums, fast steady rolls of medium length.

**Habitat.** Inhabits evergreen forest, semi-deciduous forest, secondary mixed bamboo forest, secondary forest and scrub; bamboo is particularly favoured. Occurs up to 1200 m, but usually found below 1000 m.  
**Food and Feeding.** Mainly ants, larvae of beetles, and other insects. Often in pairs or small family parties. Forages mainly in lower levels, on trunks of smaller trees, and particularly on large bamboo. Rarely visits canopy, fallen logs or ground.  
**Breeding.** Mar-May. Nest-cavity excavated 1-6 m up in dead tree, rotten stump or bamboo. Clutch 3 eggs. No other information.  
**Movements.** Resident.  
**Status and Conservation.** Not globally threatened. Very rare in Nepal, only few records (from E), where not discovered until 1974; uncommon in India and Bhutan; rare, perhaps extinct, in Bangladesh, only 1 recent record; rare to uncommon in SE Asia; uncommon in China. Occurs in Manas Wildlife Sanctuary in Bhutan, and in Nam Bai Cat Tien National Park, in Vietnam. Habitat loss could become a problem for this species, which appears to be dependent on certain environmental features, especially bamboo.  
**Bibliography.** Ali & Ripley (1983), Ali *et al.* (1996), Bangs & Van Tyne (1931), Choudhury (2001), Delacour (1951b), Delacour & Jabouille (1940), Duckworth *et al.* (1999), Eames & Robson (1992), Étiénnéopar & Hue (1978), Evans & Timmins (1998), Grimmett *et al.* (1998, 2000), Harvey (1990), Inskipp, C. & Inskipp (1991), Inskipp, C. *et al.* (1999), Inskipp, T. *et al.* (1996), Kazmierczak (2000), King *et al.* (2001), Lekagul & Round (1991), MacKinnon & Phillips (2000), Ripley (1982), Robson (2000), Robson *et al.* (1993a), Round (1988), Shrestha (2000), Smythies (1986), Stepanyan (1995), Thewlis *et al.* (1998), Thompson *et al.* (1993), Zhao Zhengjie (1995).

204. Bamboo Woodpecker

*Gecinulus viridis*

**French:** Pic des bambous **German:** Rotscheitel-Bambusspecht **Spanish:** Pito del Bambú Sureño

**Taxonomy.** *Gecinulus viridis* Blyth, 1862, Toungou, south Myanmar. Forms a superspecies with *G. grantia*, and the two are sometimes treated as conspecific. Birds from Peninsular Malaysia, tending to be a shade darker, with narrower wingbars, females also with more uniform crown and nape, are sometimes separated as race *robinsoni*; some individuals from northern populations, however, show similar variation, and recognition of geographical races seems unwarranted. Monotypic.  
**Distribution.** S & SE Myanmar, Thailand (except C) and N Laos, S to Tenasserim and Peninsular Malaysia.  
**Descriptive notes.** c. 25-26 cm. Male has red crown to nape, rest of head buff-brown, tinged yellow, more golden-green on rear crown side and neck side, darker and browner on chin; upperparts, including wing-coverts and tertiaries, dull yellowish-green with strong bronzy cast, rump and uppertail-coverts with dark crimson feather tips; primaries and secondaries dark brown, narrowly edged greenish on outer webs, rather ill-defined pale bars (sometimes stronger on primaries); uppertail blackish-brown, underwing brown, feathers tipped dull red, more extensively reddish (larger tips) on belly and flanks, almost entirely deep red on undertail-coverts; underwing brown, flight-feathers barred whitish; undertail brown, paler sides; long bill strongly chisel-tipped, slightly curved on culmen, broad across nostrils, pale yellow, greener base; iris deep red-brown or brown; legs dark slaty. Female is slightly shorter-winged, shorter-billed, has forehead to nape blackish-brown, sometimes some paler feather bases showing. Juvenile duller and greyer than adult, red tips absent or much reduced, male with less red on head top. Voice. Long irregular series of clear whistled notes, "kwe kwe kwe" or "pwip pwip", rather similar to calls of *Picus viridis* or *P. awokera*; also common are several "kup" notes, "kyu-kyu", or "kyu-kyu-kup" calls; single "whit" notes when disturbed; nestlings have 2 distinct types of note, "kyaa" and "pip". Drumrolls vary greatly in length, from c. 0.5 seconds to more than 1 second, accelerating, rhythm slightly slower than those of *Picus canus*, c. 3 rolls per minute.  
**Habitat.** Occupies undisturbed, mature subtropical evergreen broadleaf forest in C mountain range of Yambaru; occasionally seen in secondary forest outside main range. On hilltops with large trees, down to forest edge along clearings or roads. Areas with soft, decaying wood preferred; conifers appear to be avoided.  
**Food and Feeding.** Large arthropods, beetle larvae (e.g. Cerambycidae), moths, spiders, centipedes; observed feeding gecko to nestlings. Fruits, berries and seeds (*Rhus*, *Rubus*), acorns and other nuts (*Pasania*, *Machilus*) also important in diet. Forages chiefly near the ground, mostly below 5 m, where it searches tree trunks, bamboo and fallen logs; also in canopy, especially when

edged greenish; dark olive-brown below, very slightly paler in lowermost region; underwing brownish, faint barring, coverts mottled grey and whitish; undertail brown, dull yellowish cast; fairly long bill chisel-tipped, straight or culmen slightly curved, broad across nostrils, pale yellow to whitish, grey or greenish base; iris dark red or red-brown; legs olive-green, 3 toes. Female has crown dull greenish-yellow. Juvenile resemble adult female but darker, browner above, very dark and often grey-tinged below. Voice. Single "bik" calls occasionally; most common is a dry rattle, changing in loudness and pitch, not in speed; also loud clear "kéép-kee-kee-kee-kee-kee". c. 3 notes per second; "kweek-week-week-week-week", "wee-a-wee-a-wee" or similar during encounters. Drums in loud bursts lasting c. 1 second.  
**Habitat.** Evergreen and deciduous forest with extensive clusters of large bamboo. Lowlands in N of range, 600-1400 m farther S.  
**Food and Feeding.** Ants. Feeds singly or in pairs, mainly at lower levels; only occasionally descends to ground. Forages mainly on live or dead bamboo; gleans, and probes into fractures, crevices, cracks and holes. Pecking is light, not sustained for long, producing very small round holes just above nodes of stalks; moves between nodes by gliding along the smooth surface while clasp-ing around the stalk. Movements slow and deliberate, searches substrate carefully.  
**Breeding.** Apr-May. Nest excavated at up to 5 m in bamboo, above a node, cavity c. 25 cm deep. No other details known.  
**Movements.** Resident.  
**Status and Conservation.** Not globally threatened. Generally uncommon and local, depending on habitat availability; discontinuous distribution. Occurs in Nam Nao and Kaeng Krachan National Parks and Khao Nor Chuchi Reserve (Thailand). This species' specialized habitat requirements could make it vulnerable to extensive changes in the environment. Habitat loss could become a major problem for this woodpecker.

Genus *SAPHEOPIPO* Hargitt, 1890

205. Okinawa Woodpecker

*Sapheopipo noguchii*

**French:** Pic d'Okinawa **German:** Okinawaspecht **Spanish:** Pito de Okinawa  
**Other common names:** Pryer's Woodpecker

**Taxonomy.** *Picus noguchii* Seebohm, 1887, Okinawa, Ryukyu Islands. Monotypic.  
**Distribution.** Okinawa, in S Ryukyus.

**Descriptive notes.** 31-35 cm. Male has fore-head to nape red with blackish feather bases visible, pale buffish-brown nasal tufts, lores and line above eye, darker and browner ear-coverts and neck side with deep brown streaking, suggestion of darker stripe in malar region; chin to upper breast paler grey-brown, hint of whit-ish coloration; hindneck and upperparts rich dark brown, dull red feather tips, these most obvious on rump and uppertail-coverts; underwing very dark brown, flight-feathers edged reddish, small white bar-like spots on outer primaries and on inner webs of inner pri-maries and secondaries; uppertail blackish-

brown; dark brown below, feathers tipped dull red, more extensively reddish (larger tips) on belly and flanks, almost entirely deep red on undertail-coverts; underwing brown, flight-feathers barred whitish; undertail brown, paler sides; long bill strongly chisel-tipped, slightly curved on culmen, broad across nostrils, pale yellow, greener base; iris deep red-brown or brown; legs dark slaty. Female is slightly shorter-winged, shorter-billed, has forehead to nape blackish-brown, sometimes some paler feather bases showing. Juvenile duller and greyer than adult, red tips absent or much reduced, male with less red on head top. Voice. Long irregular series of clear whistled notes, "kwe kwe kwe" or "pwip pwip", rather similar to calls of *Picus viridis* or *P. awokera*; also common are several "kup" notes, "kyu-kyu", or "kyu-kyu-kup" calls; single "whit" notes when disturbed; nestlings have 2 distinct types of note, "kyaa" and "pip". Genus *REINWARDTIPICUS* Bonaparte, 1854

208. Orange-backed Woodpecker

*Reinwardtipicus validus*

French: Pic vigoureux      German: Reinwardtspecht      Spanish: Pito Dorsinaranja

**Taxonomy.** *Picus validus* Temminck, 1825, Java. In past, commonly placed in *Chrysocolaptes*. Races weakly differentiated, with much overlap in features. Two subspecies recognized.  
**Subspecies and Distribution.**  
*R. v. xanthopygius* (Finsch, 1905) - extreme S Thailand S to Sumatra and Borneo, including Riau Archipelago, Bangka I and N Natuna Is.  
*R. v. validus* (Temminck, 1825) - Java.

**Descriptive notes.** 30 cm; 155-185 g. Male has red forehead, crown and short crest bordered pale orange, orange-brown side of head, darker and browner towards rear; chin and malar area golden-brown; lower nape and hindneck white, bordered brownish-grey, mantle and back feathers extensively tipped yellow to orange, rump deeper orange to red with yellow-olive suffusion, variable brownish barring; uppertail-coverts dark brown to dull orange; scapulars and wing-coverts black-brown; flight-feathers blackish, 3-5 broad rufous-chestnut bars across all feathers, spots on primary coverts; uppertail very dark brown; side of neck, foreneck and

most of underbody brown, broad deep red feather tips creating red appearance, narrowly edged yellowish on flanks and lower regions, ventral area grey-brown, dark brown on undertail-coverts and undertail; underwing barred brownish or cinnamon, coverts sometimes paler buffish and barred brown; long bill slightly curved, broad-based, distinct chisel tip, light brown, yellowish lower mandible; iris brownish to orange-red; legs brownish to grey. Female has forehead to nape and crest dark brown, side of head grey-brown, hindneck and upperparts white or off-white, rump brownish, narrow band on side of neck tinged rufous, foreneck and underparts dark grey-brown with obscure paler barring on flanks and belly. Juvenile much as female, but young male usually has some red on crown and often hint of yellow-orange on rump. Race *xanthopygius* usually has less red on rump of male than nominate (but much overlap between races), no brown barring on back and rump. Voice. Various loud, ringing calls, e.g. "pit", singly or in loose irregular series; slow regular "kit kit kit kit kit-it" series of c. 9 elements, terminating with double call rising sharply; other, higher-pitched, more irregular series may commence with lower note; much faster series of "pit" notes as rattle call; loud rapid "wheet-wheet-wheet-wheet-wheow" or "polleet, polleet" and excited "towelitit-towelitit, cha-cha" also described. Drums weakly, bursts very short.

**Habitat.** Primary or secondary evergreen rainforest, coastal vegetation, mature plantations; also along forest edge, and in clear-cuts with single dead trees. Lowlands, extending uncommonly to hilly country throughout range; below 1000 m in Thailand and Peninsular Malaysia, where most common below 700 m; in lowlands, occasionally in montane habitats to 2200 m, in Java; common in lowland forests of Borneo, where has also been found to 2000 m.

**Food and Feeding.** Beetle larvae, termites (Isoptera), caterpillars, ants and other insects. Lives in pairs and family parties. Forages in very low (rarely) and middle strata, and in canopy as well. Attacks rotting logs on the ground, also dead stumps, tree trunks and larger branches; even visits thin vines. Pecks and hammers with loud blows to excavate substrate, sometimes spends minutes to excavate at a single site. Often removes bark with lateral strokes, or quickly opens holes in bark. Moves rapidly along trunk and branches. Trees, stumps and logs searched systematically; tends not to move great distances between foraging locations.

**Breeding.** Jan-Sept; insufficient data on regional differences; in N Borneo (Sabah) nest with young in late Mar, another nest being built in Apr. Displays include crest-raising, bill-directing, wing-flicks, wing-spreading and swinging head movements, associated with many vocalizations. Nest-hole excavated c. 5 m up in dead tree. Clutch 1 or 2 eggs; incubation and fledging periods not documented; fledglings fed by parents directly, not by regurgitation.

**Movements.** Resident.  
**Status and Conservation.** Not globally threatened. Uncommon or scarce in most of its range; rare in Java, but commoner in Sumatra and Borneo. Occurs in Khao Nor Chuchi Reserve (Thailand), Taman Negara National Park (Peninsular Malaysia), Gunung Leuser and Way Kambas National Parks (Sumatra), Gunung Gede-Pangrango National Park (Java) and Mount Kinabalu National Park (Borneo).

**Bibliography.** Andrew (1985, 1992), van Balen (1999), Bucknill & Chasen (1990), Castelletta *et al.* (2000), Duckworth & Kelsh (1988), Duckworth *et al.* (1997), Fogden (1976), Ford & Davison (1995), Holmes (1996), Hutchinson (1950), Inskipp *et al.* (1996), Jepson & Brinkman (1993), Jeyarajasingam & Pearson (1999), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Philipps (1993), van Marle & Voous (1988), Medway & Wells (1976), Nash & Nash (1986, 1988), Pearson (1975a), Riley (1938), Robson (2000), Sargeant (1997), Short (1973d), Smythies (1999), Vowles & Vowles (1997), Wells (1985, 1999), Wilkinson, Dutson & Sheldon (1991).

Tribe MEIGLYPTINI

Genus *MEIGLYPTES* Swainson, 1837

209. Buff-rumped Woodpecker

*Meiglyptes tristis*

French: Pic strihup      German: Braunbürlspecht      Spanish: Pito Triste  
Other common names: Fulvous-rumped (Barred) Woodpecker

**Taxonomy.** *Picus tristis* Horsfield, 1821, Java. Named races *micropterus* (Borneo) and *microterus* (Nias I) considered synonymous with *grammithorax*. Two subspecies recognized.  
**Subspecies and Distribution.**  
*M. t. grammithorax* (Malherbe, 1862) - S Myanmar (S Tenasserim) and peninsular Thailand S to Sumatra, including islands of Nias and Bangka, N Natunas, and Borneo (including Banggai I and islands off NE coast).  
*M. t. tristis* (Horsfield, 1821) - Java.

**Descriptive notes.** 17-18 cm; 31-50 g. Distinctive small, short-tailed woodpecker. Male has short red malar patch; rest of head, crest and neck to upper breast greyish-brown with narrow paler vermiculations, these are usually less pronounced or lacking in fore area, pale buff eyering, lores and area around bill base; upperparts barred blackish and white, rump creamy; upperwing black with white bars, broadest on covert tips and on inner webs of flight-feathers; uppertail black, thin whitish barring; lower breast and rest of underparts blackish, some white on flanks, sometimes a few bars; underwing blackish, buffish-white

coverts; undertail brown, narrowly barred buff; longish bill narrow-based, rather pointed, culmen curved, black; iris deep brown; legs grey to greenish. Female lacks red malar. Juvenile as adult, but dark areas duller, more brownish, bars usually broader. Race *grammithorax* has much more buff plumage, and entire underparts closely barred. Voice. Single "pit" or "chit", also as double click or in loose series, from mildly excited birds or in flight; also much longer "pee", apparently as alarm; "wicka" calls in encounters between sexes recall similar vocalizations of American *Colaptes*; soft rattle, "drrrrrrrrr", as long-distance communication, is higher-pitched than corresponding vocalization of *M. tukki*, can last over 2 seconds, has wavering quality (rises in pitch around middle). Drumming weak, 18 to over 40 beats at rate of 15 per second, faster at beginning, slower later, roll lasts for 1-5-3 seconds.

**Habitat.** Primary and secondary forests; found in rather open coastal habitats as well as in inland forest. Most common at forest edges, around clearings, in areas of second growth within forest, and in second growth. Also frequents mature rubber stands, and orchards. From lowlands to 600 m in Thailand, to 800 m in Peninsular Malaysia; to 1100 m in other parts of mainland SE Asia.

**Food and Feeding.** Ants, other insects. Often in pairs, members of which keep more or less in close contact; may join mixed-species flocks. Forages in canopy of tall trees, on twigs and distal ends of branches, and in saplings and smaller trees; feeding sites often several trees apart. Gleaning with occasional probing the commonest techniques, with food items gathered from bark and from tips and leaves of tiny twigs; rarely pecks, and then weakly. Moves rapidly, and frequently perches crosswise or hangs upside-down.

**Breeding.** Season not well known. Mar-Apr, probably to Jul. Both sexes display with head-swinging. Nest-hole excavated by both sexes, can be low, below 2 m, or higher up, 8-15 m, and in live tree or dead stump. Clutch 2 eggs; no details on incubation and fledging periods.

**Movements.** Resident.  
**Status and Conservation.** Not globally threatened. Common to fairly common in most of range; however, extinct in Singapore. Nominative race of Java is rare, possibly extinct, with no recent records. Occurs in several protected areas, e.g. Khao Nor Chuchi Reserve (Thailand), Panti Forest Reserve (Peninsular Malaysia), Way Kambas National Park (Sumatra) and Danum Valley Conservation Area (Borneo).

**Bibliography.** Andrew (1992), van Balen (1999), Bucknill & Chasen (1990), Castelletta *et al.* (2000), Chasen & Hoogerwerf (1941), Duckworth & Kelsh (1988), Duckworth *et al.* (1997), Dymond (1994), Ford & Davison (1995), Hellebrekers & Hoogerwerf (1967), Holmes (1994), Jeyarajasingam & Pearson (1999), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Philipps (1993), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Meyer de Schauensee & Ripley (1940), Nash, A.D. & Nash (1985), Nash, S.V. & Nash (1988), Riley (1938), Robinson & Kloss (1924a), Robson (2000), Sargeant (1997), Short (1973d), Smythies (1986, 1999), Stresemann (1921a), Vowles & Vowles (1997), Wells (1985, 1999), Wilkinson, Dutson & Sheldon (1991).

210. Black-and-buff Woodpecker

*Meiglyptes jugularis*

French: Pic à jugulaire      German: Dommelspecht      Spanish: Pito Blanquinegro

**Taxonomy.** *Picus (Meiglyptes) jugularis* Blyth, 1845, Arakan and Tenasserim, Myanmar. Monotypic.  
**Distribution.** SW, S & E Myanmar, including Tenasserim, much of Thailand (except C), and Indochina except Tonkin.

**Descriptive notes.** c. 22 cm; 50-57 g. Small, short-tailed woodpecker. Male has short malar stripe of dark red feather tips, often appearing barred red and black, lores mainly buff, often with black barring; rest of head black, narrowly barred pale buff, hindcrown and nape feathers plain black and elongated to form long crest; hindneck and side of neck creamy; upperparts black, mantle sometimes with a few pale bars, rump white to buffish-white, inner scapulars black, outers mainly white to pale cream-buff; upperwing mostly black, coverts tipped creamy, flight-feathers with thin white to buff bars, broader on inner webs, white to pale cream-buff

tertiaries with prominent broad dark bars on distal parts, variable; uppertail black; throat black, variably barred buff, can appear chequered; rest of underparts black to brown-black, sometimes 2 or 3 whitish bars on lower flanks, rarely also on belly; underwing dusky, black tip and whitish bars, coverts creamy; fairly long bill narrow-based, slightly chisel-tipped, culmen strongly curved, black, often slightly paler base of lower mandible; iris brown; legs grey-green or grey-blue. Female lacks red in malar, which instead is barred black and buff. Juvenile as adult but duller, head more clearly barred. Voice. Nasal "ki-yew", and series as "tititi-wéek week week".

**Habitat.** Evergreen forest; often shows distinct preference for more open areas, such as edges and clearings, also bamboo; often seems to avoid dense forest. Lowlands, in forested areas to 900 m, occasionally 1000 m.

**Food and Feeding.** Ants, other insects. Feeds singly or in pairs; not noted in association with other species. Often hangs upside-down on small leafy twigs and branches in lower and middle stores. Habits not well known, but appear to be similar to those of *M. tristis* and *Hemicircus canente*.

**Breeding.** Mar-Jun. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally fairly common. Occurs in Khao Yai and Kaeng Krachan National Parks and Khao Nor Chuchi Reserve (Thailand), and in Nam Bai Cat Tien National Park (Vietnam). Poorly known. Research required to determine its feeding ecology and breeding biology.

**Bibliography.** Deignan (1945), Delacour & Jabouille (1940), Duckworth *et al.* (1999), Eames & Ericson (1996), Eames & Robson (1992), Evans & Timmins (1998), Lekagul & Round (1991), Riley (1938), Robson (2000), Robson *et al.* (1993a), Smythies (1986), Stepanyan (1995), Wheatley (1996).

## 211. Buff-necked Woodpecker

### *Meiglyptes tukki*

**French:** Pic tukki

**German:** TukkiSpecht

**Spanish:** Pito Tukki

**Other common names:** Buff-necked Barred Woodpecker

**Taxonomy.** *Picus tukki* Lesson, 1839, Sumatra.

N Natunas population, sometimes separated as race *azaleus*, may show more obscure barring, but much variation and separation not warranted; similarly, described race *calceuticus* (Banyak Is, off NW Sumatra) appears indistinguishable from nominate. Five subspecies recognized.

**Subspecies and Distribution.**

*M. t. tukki* (Lesson, 1839) - S Myanmar (S Tenasserim) and peninsular Thailand S to Sumatra, nearby Banyak Is, Bangka, N Natunas and N Borneo.

*M. t. infuscatus* Salvadori, 1887 - Nias I (off NW Sumatra).

*M. t. batu* Meyer de Schauensee & Ripley, 1940 - Batu Is (off NW Sumatra).

*M. t. pulonis* Chasen & Kloss, 1929 - Panggi I (off N Borneo).

*M. t. pernerpes* Oberholser, 1924 - S Borneo.

**Descriptive notes.** c. 21 cm; 43-64 g. Male has red malar patch barred black and buffy at rear, large buffish-white or yellowish-buff patch from lower edge of rear ear-coverts to rear throat side; rest of head, including short crest, dark grey-brown or olive-brown, forehead often slightly paler or, rarely, with hint of red, sometimes somewhat darker indistinct eye-stripe; chin and throat barred blackish-brown and buff; entire upperparts and uppertail dull dark olive-brown, all narrowly barred buff, wing-coverts occasionally edged dull red; flight-feathers dark brown, narrowly barred buff, bars broader and paler (whitish) on inner

webs; lower throat and upper breast blackish-brown, sometimes obscured by barring; rest of underparts brown, narrowly barred buff, bars slightly broader on flanks, often only vague on belly centre; underwing brown, pale coverts and bases of flight-feathers; moderately long bill fairly narrow-based, pointed, culmen strongly curved, black, paler lower mandible; iris deep crimson, red-brown or brown; legs grey-green to grey-brown. Female lacks red in malar region. Juvenile has pale bars broader, dark throat patch less well defined, male with reddish malar, sometimes red tips to forehead and, less often, crown feathers. Race *pernerpes* is strongly barred, browner, without olive tinges, often with more rusty or reddish tone than nominate; *batu* has blackish crown, more contrasting blackish breast patch; *pulonis* is much longer-billed than others, also browner than nominate, less olive, with paler throat; *infuscatus* is slightly shorter-winged than others, also barring weak, pale bars tending to be obscured, dark crown. Voice. Single "pee" calls like those of *M. tristis*, also series of "dwt" or "ki-ti" and "wick-wick-wick-wick" during encounters; commonest vocalization is high-pitched trill, "krr-r-r", lower in pitch, longer and slower than that of *M. tristis*. Both sexes drum, single roll may last less than 1 second or over 3 seconds and contain from c. 12 to almost 60 beats, initial section of longer bouts and shorter bouts delivered at faster rate than the final one.

**Habitat.** Primary and tall secondary evergreen and semi-evergreen forest with dense undergrowth and rotting stumps; also peat-swamp-forest. Less often at forest edges and clearings than *M. tristis*. Lowlands; generally below 600 m, occasionally to 1200 m, in mainland SE Asia; reaches 1000 m in Greater Sundas.

**Food and Feeding.** Ants and termites (Isoptera). Feeds singly, in small groups, or in pairs, partners sometimes staying in close contact, even feeding side by side; regularly joins mixed-species flocks. Generally forages in middle and lower strata of forest, often comes down into low bushes and saplings, visiting overgrown gulleys and similar; altogether, exploits more diverse sites than does *M. tristis*. Higher strata visited mainly when with other birds. Forages on branch tips and leaf buds in crown of tall trees, also visits larger branches and trunks and decayed logs of the understorey. Predominant foraging technique is gleaning: some probing, pecking and working at dead wood. Movements rapid; in most cases, spends only little time at a single spot or tree.

**Breeding.** Feb-Jul; May-Jun in Peninsular Malaysia; young found in early Jun in Borneo. Head-swinging displays. Nest built in rotten wood in live tree, or low in tree stump, at 1.5-5 m. Clutch 2 eggs; chicks fed by both parents, apparently by regurgitation; no details of incubation and fledging periods. Recorded longevity 5 years, 3 months.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Uncommon to fairly common in continental range; perhaps commoner elsewhere. Occurs in Taman Negara National Park (Peninsular Malaysia) and Kerinci-Seblat and Way Kambas National Parks (Sumatra); fairly common in Danum Valley Conservation Area (Borneo). Within this species' range, massive destruction of lowland forest has already taken place, especially in the Sundas, where primary forest is likely to have disappeared by 2010; significant habitat loss also a major problem in Thailand and Peninsular Malaysia. Although it appears to have a reasonable population in the higher parts of its range, and can also be found in secondary growth, extension of deforestation to more elevated parts of the region could quickly place this woodpecker, as well as many other wildlife species, at considerable risk.

**Bibliography.** Andreev *et al.* (2001), Andrew (1992), Bucknill & Chasen (1990), Castelletta *et al.* (2000), Chasen (1937), Chasen & Hoogerwerf (1941), Duckworth & Kelsch (1988), Duckworth *et al.* (1997), Dymond (1994), Holmes (1994, 1996), Inskipp *et al.* (1996), Jepson & Brinkman (1993), Jeyarajasingam & Pearson (1999), Lekagul & Round (1991), MacKinnon & Phillips (1993), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Nash & Nash (1988), Riley (1938), Robinson & Kloss (1924a), Robson (2000), Short (1973d), Smythies

(1986, 1999), Stattersfield & Capper (2000), Vowles & Vowles (1997), Wells (1985, 1999), Wilkinson, Dutton & Sheldon (1991), Wong (1985).

## Genus *HEMICIRCUS* Swainson, 1837

### 212. Grey-and-buff Woodpecker

#### *Hemicircus concretus*

**French:** Pic trapu

**German:** Kurzschnanzspecht

**Spanish:** Pito Colicorto

**Other common names:** Grey-breasted Woodpecker(!)

**Taxonomy.** *Picus concretus* Temminck, 1821, Java.

Sumatra and Borneo populations named as race *comometopus*, but insufficiently different from *sordidus* to warrant separation. Two subspecies recognized.

**Subspecies and Distribution.**

*H. c. sordidus* (Eyton, 1845) - S Myanmar (S Tenasserim) and peninsular Thailand S to Sumatra (including N Mentawai I and Bangka I), and Borneo.

*H. c. concretus* (Temminck, 1821) - W & C Java.

**Descriptive notes.** 13-14 cm; 27-32 g. Very small and compact woodpecker, with slender neck, large head and extremely short, rounded tail. Male has red forehead, crown and crest; rest of head and neck dark grey, apart from whitish hindneck and thin pale line on malar area and down side of neck; upperparts dark brownish-black, feathers broadly edged and tipped buffish-white to white, rump whitish (normally stained buff by glandular secretion), black uppertail-coverts tipped white; tertials black with whitish edges and tips, or whitish with large black heart-shaped spots; flight-feathers black, inner webs of primaries edged

buffish-white, secondaries with a few whitish bars; uppertail black, sometimes paler bars on outer feathers; grey of head and neck extends over underparts, blacker in lower region, variably barred buffish on flanks and undertail-coverts; underwing blackish, buff patch at base of primaries, coverts buffish or barred black and white; longish bill straight, chisel-tipped, rather broad base, greyish-black; iris red-brown; legs dark brown. Female has shorter bill than male, has top of head dark grey, not red. Juvenile has broader and more rufous edges and tips above, underparts more heavily barred with pale rufous-buff, top of head cinnamon-rufous with narrow black tips, male with orange-red crest, female with less red. Race *sordidus* is slightly smaller and paler grey than nominate, has rear of crest grey, not red; juvenile has buff crown. Voice. Sharp "chick", "pit" or "tsip", slightly higher-pitched and louder than calls of *Meiglyptes tristis*; similar but longer "peew", "ki-oo", "ki-yow", or "kee-yew" notes, barely distinguishable from corresponding calls of *H. canente*, during encounters; vibrating "chitter" in agonistic situations and during aerial chases. Drums weakly.

**Habitat.** Evergreen forest, especially evergreen secondary forest, forest edge, also gardens and plantations; seems to favour habitat with bamboo. To 1100 m in SE Asia, up to 1500 m in Borneo.

**Food and Feeding.** Insects; fruits, such as lime and mistletoe (*Loranthus*), also recorded in diet. Singly, in pairs, sometimes in groups (up to 10 individuals observed together); also joins mixed-species flocks. Forages in treetops, among twigs and leaves, as well as on trunks and branches; attracted to trees projecting above the rest of the vegetation, even when isolated in open area. Occasionally in bushes. Main foraging technique is gleaning; frequently pecks, too, more so than *Meiglyptes*; also pries off bark, and probes. Usually moves rapidly in dense foliage of the canopy, flits between twigs, branches and leaf clusters; hops, twists, peers under leaves, clings like tit (Paridae) to twigs and fruits. When moving along trunks, darts about in all directions, can move almost straight downwards, head first. Possible sexual differences in foraging in terms of micro-habitat selection and relative use of foraging techniques, but insufficiently documented. Flies long distances, including over open areas, between feeding sites.

**Breeding.** Dec-Jul; apparently Apr-Jul in Peninsular Malaysia, and May-Jun in Java. Crest-raising is commonest display. Nest-hole excavated in tree, at heights between 9 m and 30 m. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon throughout most of range; locally common in Sumatra, possibly also Borneo; extinct Singapore. Occurs in Khao Nor Chuchi Reserve (Thailand) and Way Kambas National Park (Sumatra). Poorly known; requires field study.

**Bibliography.** Andrew (1992), van Balen (1999), van Balen & Prentice (1978), Bucknill & Chasen (1990), Castelletta *et al.* (2000), Duckworth & Kelsch (1988), Duckworth *et al.* (1997), Ford & Davison (1995), Grantham (2000), Hellebrekers & Hoogerwerf (1967), Holmes (1994), Inskipp *et al.* (1996), Jensen & Bahr (2000), Jeyarajasingam & Pearson (1999), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Phillips (1993), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Meyer de Schauensee & Ripley (1940), Nash, A.D. & Nash (1985), Nash, S.V. & Nash (1988), Riley (1938), Robinson & Kloss (1924a), Robson (2000), Sargeant (1997), Short (1973d), Smythies (1986, 1999), Stresemann (1921a), Vowles & Vowles (1997), Wells (1985, 1990, 1999), Wilkinson, Dutton & Sheldon (1991).

### 213. Heart-spotted Woodpecker

#### *Hemicircus canente*

**French:** Pic canente

**German:** Rundschwanzspecht

**Spanish:** Pito de Corazones

**Taxonomy.** *Picus canente* Lesson, 1830, Pegu, Myanmar.

Clinal increase in size from SW to NE India, but differences negligible; individual variation fairly marked, but no significant geographical pattern; as a result, proposed race *cordatus* (W India) is unsustainable. Monotypic.

**Distribution.** W & NE peninsular India, Bangladesh; and from SW, S & E Myanmar, and S Annam, S to S Thailand, Cambodia, and CochinChina.

**Descriptive notes.** 15-16 cm; 37-50 g. Very small, compact woodpecker with thin neck, large head with prominent crest, and strikingly short and rounded tail. Male has black head and hindneck,

very small white spots or speckles on forehead and forecrown; throat and side of neck white, tinged buff or cream, olive-grey or buffish-grey on lower throat and breast; upperparts except rump black, sometimes some white bars on back or uppertail-coverts, rump white or off-white (special gland produces secretion causing buff staining); inner scapulars black, outer scapulars, tertials, lesser and median coverts and variable number of inner greater coverts white to buffish-white with large, black heart-shaped marks, remaining coverts black with thin white edges and tips; flight-feathers black, narrowly edged

white on inner webs; uppertail black; belly and undertail-coverts black (sometimes very narrowly barred), rarely entire underparts, including breast, black; underwing blackish, white coverts and base of primaries; long bill relatively slender but broad-based, with chisel tip, dark brown to blackish; iris brown to dull red-brown; legs brown, or tinged greenish. Female has shorter bill and shorter wing than male, and also differs in having white or buffish-white forehead and forecrown. Juvenile similar to adult female, but pale areas more buffy, less white, forehead often partly barred black, usually darker below, including throat, but always at least some white on side of neck. **VOICE.** Squeaky nasal "ki-yew", "chirrick" or "ch-yew", emphasis on second syllable, repeated several times, very like corresponding call of *H. concretus*; also, high-pitched "kee-kee-kee-kee" and long-drawn grating "chur-r"; "su-sie" notes in display. Drums weakly, infrequently.

**Habitat.** Moist and dense deciduous and evergreen forests, at forest edge, in secondary forest, bamboo, and open deciduous forest; particularly fond of bamboo and coffee plantations (and teak) in W of range, and shows similar liking for bamboo in Cochinchina. Lowlands, from plains up to 900 m and 1000 m in SE Asia, to 1300 m in India.

**Food and Feeding.** Ants, termites (Isoptera), larvae, and other insects comprise bulk of diet. Usually singly or in pairs, or in mixed-species parties. Forages on twigs in canopy, also on trunks and higher dead branches; gleans, pecks and hammers. Often perches crosswise on twig; moves rapidly along twigs and branches. Observed pecking holes in dry pods of *Cassia fistula* to extract insect larvae. Significant morphological differences between the sexes suggest differences in foraging behaviour, but no quantitative data exist.

**Breeding.** Nov-Apr. Displays with bowing or bobbing movements and associated vocalizations. Tiny nest-hole excavated in dead branch, occasionally fence post, usually low down, 1-4 m, but occasionally much higher, to 12 m or more. Clutch 3 eggs, less commonly 2; no other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Sparsely distributed in India, locally more frequent; no recent records from Bangladesh, last recorded in 1984, possibly extinct; fairly common in SE Asia. Occurs in numerous protected areas, e.g. Indira Gandhi and Periyar National Parks and Thunakadavu Reserve (India), Khao Yai, Nam Nao and Kaeng Krachan National Parks (Thailand) and Nam Bai Cat Tien National Park (Vietnam).

**Bibliography.** Ali (1951a, 1996), Ali & Ripley (1983), Betts (1934), Bock & Short (1971), Champion-Jones (1938), Chazee (1994), Deignan (1945), Delacour & Jabouille (1940), Eames (1995), Eames & Robson (1992), Evans & Timmins (1998), Goes (1999), Gokula & Vijayan (1997), Grimmett *et al.* (1998), Harvey (1990), Inglis (1931), Kannan (1998), Kazmierczak (2000), Lainer (1999), Lekagul & Round (1991), Meyer de Schauensee (1946b), Riley (1938), Ripley (1982), Robson (2000), Robson *et al.* (1993a), Santharam (1998b, 1998c), Short (1973d), Smythies (1986), Stepanyan (1995), Thompson *et al.* (1993), Wells (1999).

## Family PICIDAE (WOODPECKERS) SPECIES ACCOUNTS

### PLATE 49

## Genus *MULLERIPICUS* Bonaparte, 1854

### 214. Ashy Woodpecker

#### *Mulleripicus fulvus*

**French:** Pic fauve

**German:** Celebesspecht

**Spanish:** Picatronicos de Célebes

**Other common names:** Fulvous/Celebes Woodpecker

**Taxonomy.** *Picus fulvus* Quoy and Gaimard, 1830, Sulawesi.  
Two subspecies recognized.

#### **Subspecies and Distribution.**

*M. f. fulvus* (Quoy and Gaimard, 1830) - N Sulawesi, including islands of Manterawu and Lembah, and archipelagos of Banggai and Togian.

*M. f. wallacei* Tweeddale, 1877 - S Sulawesi, including Muna I and Buton I.

**Descriptive notes.** c. 40 cm. Large, long-tailed woodpecker. Male has dark red on forehead, lores, cheeks and malar area, red usually to central crown and front of ear-coverts, but often more re-

stricted at rear, sometimes a few dark feather bases visible, e.g. forming dark line on lores; dark grey rear head and hindneck, and paler grey-buff chin, throat and foreneck, all with very small whitish spots; upperparts dark grey-brown to blackish-slate, a little paler on tail-coverts, ■ shade darker on wings, occasionally some pale spots or shaft streaks (especially on tail-coverts); uppertail dark grey-brown to blackish-grey; rich buff to creamy yellowish-brown below, rather greyer on breast, often washed yellow-grey on flanks (underparts frequently stained dark reddish or ochre by foraging activities); underwing pale brownish-

grey to dark grey; undertail pale brown to grey, washed yellow; long bill slightly chisel-tipped, culmen curved, narrow across nostrils, black; iris pale yellow, orbital-skin grey; legs greenish-grey, or tinged bluish. Female has red of head replaced by dark grey, all but forehead very finely spotted pale. Juvenile much as adult but duller, more spotted, with red on face, male with less than adult, red on female even less. Race *wallacei* has slightly longer wing and longer tail than nominate, but shorter bill, plumage perhaps a shade paler, red on head of male brighter and far more extensive.

**Voice.** Laughing rapid “hew-hew-hew-hew-hew” or “tuk tuk tuk”, muffled, not loud. Drums in breeding season.

**Habitat.** Inhabits primary and secondary forest; prefers closed forest, but seen regularly in forest patches on the Lanowulu savanna. Rarely close to habitation. From lowlands to mountains, up to 2200 m.

**Food and Feeding.** Termites (Isoptera), caterpillars; presumably also other arthropods. In pairs, or family groups of up to 5 birds. Most commonly seen foraging on tree trunks. Indirect evidence indicates at least occasional ground-foraging; probably breaks into termite mounds.

**Breeding.** A few observations and evidence from specimens indicate nesting in Mar-Aug. Nest-hole excavated in dead tree or in dead part of live tree; one hole watched during excavation was c. 12 m above ground, entrance facing away from morning sun, male did 75% of work. Clutch 2-3 eggs; other details not known.

**Movements.** Probably resident.

**Status and Conservation.** Not globally threatened. Not uncommon. Occurs in Manembonembo, Gunung Ambang and Tangkoko Nature Reserves, Dumoga-Bone, Lore Lindu and Rawa Aopa National Parks. In Gunung Ambang, common at L. Iloloi. Seems to be reasonably common, and unlikely to become threatened in near future, as long as habitat is conserved.

**Bibliography.** Andrew (1992), Andrew & Holmes (1990), Baltzer (1990), Caterall (1997), Coates & Bishop (1997), Ekstrom *et al.* (1998), Holmes & Phillips (1996), Inskipp *et al.* (1996), Riley & Mole (2001), Rozendaal (1989), Wardill (1995), Wating (1983), Wheatley (1996), White & Bruce (1986).

215. Sooty Woodpecker

*Mulleripicus funebris*

**French:** Pic en deuil      **German:** Philippinenspecht      **Spanish:** Picatronsos Filipino  
**Other common names:** Tweeddale’s Woodpecker (*fuliginosus*)

**Taxonomy.** *Picus funebris* Valenciennes, 1826, Philippines. In past, race *fuliginosus* was considered a separate species. Races *mayri* and *parkesi* differ little from nominate, and might be better synonymized. Four subspecies currently recognized.

**Subspecies and Distribution.**

- M. f. mayri* Gilliard, 1949 - N Luzon.
- M. f. funebris* (Valenciennes, 1826) - C & S Luzon, Marinduque and Catanduanes.
- M. f. parkesi* Manuel, 1957 - Polillo Is.
- M. f. fuliginosus* Tweeddale, 1877 - Samar, Leyte and Mindanao.

**Descriptive notes.** 30 cm; 139-183 g. Male has dark red forehead and forecrown, lores, cheeks, malar region and front of ear-coverts, usually some black feather bases showing, sometimes red not extending far on to crown; rest of head and neck black, sometimes slightly greyish on throat, finely speckled with white (spots sometimes lacking); entire upperparts, including wings and tail, blue-glossed black; underparts slightly paler, more sooty-black, unglossed, rarely a few small pale spots on breast; in worn plumage, browner and less glossy, fewer or no spots, black feather bases more visible on face; longish bill almost pointed, culmen curved,

narrow across nostrils, blackish, pale horn-yellow at side; iris pale yellow; legs brownish-grey. Female has entire head blackish with fine white spots, spots sometimes few or absent. Juvenile as adult, but duller and browner, without gloss, pale spots bigger but less sharp, male with red face like adult. Race *mayri* tends to have longer bill and longer tail than nominate, but considerable overlap in measurements, bill yellowish-grey or ivory-yellow with grey base; *parkesi* is very like nominate, perhaps on average slightly larger, red on male’s head not reaching to forecrown; *fuliginosus* has shorter tail, differs from others in greyer, less black, coloration, more slate-grey than black above, greyer below, male with red restricted to broad malar band (occasionally traces elsewhere on head), bill relatively short and deep. **Voice.** Distinctive trill, “chil-lel-lel-lel-lel”, c. 1 second long, repeated at irregular intervals, sometimes every 5-10 seconds.

**Habitat.** Evergreen forest, secondary forest, forest edge, and near cultivations; also montane oak (*Quercus*) and pine (*Pinus*) forest above 300 m, to 1000 m, occasionally or locally to c. 1350 m.

**Food and Feeding.** No information on diet. Usually singly or in pairs, members of which maintain frequent vocal contact. Forages in upper storeys, above 20 m, in tall trees, both live ones and partly or fully dead ones; also descends to understorey, on tree trunks and large limbs.

**Breeding.** Specimens with enlarged gonads in Mar, and recently fledged juvenile seen in May; season reported as Mar-May in N (Luzon, Polillo) and Apr-Aug in S (Samar, Leyte). Nest and eggs not described.

**Movements.** Probably resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally fairly common. Occurs in Quezon National Park (Luzon). Very poorly known; inconspicuous in its forest habitat and may be overlooked. Field studies urgently needed, in order to determine details of its diet and feeding ecology, as well as its nesting behaviour.

**Bibliography.** Danielsen *et al.* (1994), Delacour & Mayr (1945), Dickinson *et al.* (1991), Dupond (1942), Gilliard (1949b, 1950), Gonzales (1983), Goodman & Gonzales (1990), Manuel (1957), McGregor (1909-1910), Pardo & Gogorza y González (1997), duPont (1971), Rand & Rabor (1960), Wheatley (1996).

216. Great Slaty Woodpecker

*Mulleripicus pulverulentus*

**French:** Pic meunier      **German:** Puderspecht      **Spanish:** Picatronsos Pizarroso  
**Other common names:** Himalayan Great Slaty Woodpecker (*harterti*)

**Taxonomy.** *Picus pulverulentus* Temminck, 1826, Java and Sumatra. Geographical variation not well marked, and individual variation makes racial delimitation difficult; size varies only slightly and inconstantly throughout range. Populations from NW (Nepal to N Assam) described as race *mohan* on basis of darker coloration, especially below, but some birds from Myanmar and Thailand appear identical. Races intergrade in peninsular Thailand, intermediates from which previously separated as race *celadinus*. Two subspecies recognized.

**Subspecies and Distribution.**

- M. p. harterti* Hesse, 1911 - N India (Himachal Pradesh) E through Himalayan foothills to N Myanmar and S China (S Yunnan), S to S Thailand and Indochina.
- M. p. pulverulentus* (Temminck, 1826) - peninsular Thailand S to E Sumatra and Riau Archipelago, W Java, Borneo and N Natunas, and W Philippines (Balabac, Palawan).

**Descriptive notes.** c. 50 cm; 360-563 g. Very large, the biggest Old World woodpecker, with very long bill, long neck and long tail. Male has pale red cheek patch, creamy to yellow-buff chin and throat, feathers of lower throat tipped pale red; rest of head and upperparts slate-grey with variable amount of small whitish feather tips (small pale spots often most prominent on ear-coverts and hindneck); wings and tail darker blackish-grey, very narrowly edged and tipped blue-grey; slate-grey below, slightly paler than upperparts, small pale streak-like spots on upper breast, becoming paler grey on lower belly; very long, strong bill chisel-

tipped, blackish on culmen and tip, yellowish on lower mandible and base of upper mandible; iris brown, orbital skin grey; legs blue-grey or greenish-grey. Female lacks red on cheeks and red tips on lower throat. Juvenile duller, browner, particularly above, chin and throat whiter, generally more spotted below, male with red malar larger than on adult, sometimes some red on crown. Race *harterti* is paler, less blackish. **Voice.** Loud whinnying cackle of 2-5 (most commonly 4) notes, “woikwoikwoikwoik”, initial note often slightly higher-pitched, final one distinctly lower, shorter version with consecutive notes dropping more in pitch, frequently in flight; single “dwot” calls, variable, perched or in flight; low soft mewling notes by partners at very close contacts: “ta-whit” or “dew-it” in more agonistic situations (with head-swinging). Drumming not certainly reported.

**Habitat.** Primary semi-open moist deciduous and tropical evergreen forests, adjacent secondary forest, clearings with scattered tall trees; also similar, almost park-like, woodland. Dipterocarp and teak forests preferred in some areas; mature sal (*Shorea*) forest, swamp-forest and tall mangroves. Most frequent in lowlands and lower hills below 600 m, but also occurs in montane habitats up to 1100 m (foothills of Himalayas), occasionally to 2000 m.

**Food and Feeding.** Predominantly ants; also other insects, such as larvae of wood-boring beetles. Small fruits possibly eaten at times. Usually in pairs, and regularly in noisy family parties of 4-6 birds, sometimes more (12), roaming through forest; sometimes associates with other woodpeckers, such as *Dryocopus javensis* and *Chrysocolaptes lucidis* when foraging. Forages mainly in tall trees, including solitary ones in open areas; flies long distances to reach these (thus, home range very extensive); sometimes visits smaller trees and saplings at low levels, not infrequently close to ground. Climbs trunks and larger branches slowly, pausing frequently at crevices and other depressions and cracks in bark; may perch crosswise in crown, even on small branches. Gleaning is the most frequent technique, and the long neck and bill assist it in reaching a long way out. Other foraging techniques include probing, pecking, prying-off of bark; also hammering with powerful low blows to excavate wood. Does not remain long at one spot to peck or hammer. Relatively nimble when foraging among branches, but climbs almost in “slow motion”.

**Breeding.** Mar-May in W and Mar-Aug in SE Asia. Displays include strange-looking head-swinging, head appearing to lag behind body in its swinging movement; during chases, wings extended widely, tail also spread. Nest-hole excavated by both sexes, although male does most of the work, very high up (range 9-45 m) in tree, in large trunk or branch, entrance hole c. 10 cm across; old nest occasionally reused, probably only when new one usurped. Clutch 2-4 eggs; both sexes incubate, and both feed chicks; incubation and fledging periods not known; fledged young remain with parents for some time, probably until next breeding cycle commences.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon in N Indian Subcontinent, and possibly extinct in Bangladesh, where no recent records; uncommon to fairly common, but often rather local, in SE Asia, extinct in Singapore; rare in S China; exceedingly rare in Sumatra and Java, and not likely to survive, but somewhat more common in Borneo; uncommon and decreasing in Philippines. Although generally uncommon or rare throughout its range, can be conspicuously noisy where present; not likely to be overlooked. Occurs in many protected areas, e.g. Corbett and Namdapha National Parks (India), Khao Yai and Nam Nao National Parks (Thailand), Nam Bai Cat Tien National Park (Vietnam), Taman Negara National Park and Pantl Forest Reserve (Peninsular Malaysia), Aas Purwo National Park (Java), Danum Valley Conservation Area (Borneo) and St Paul’s Subterranean River National Park (Palawan, Philippines). Extensive habitat destruction seems likely to have led to the demise of this magnificent woodpecker in Sumatra, and there seems little chance that it can fare much better in Java. Densities are naturally low, since it lives in large home ranges; it should be secure in the mainland parts of its current range, so long as reasonably large tracts of habitat remain intact.

**Bibliography.** Ali & Ripley (1983), Ali *et al.* (1996), Andrew (1992), van Balen (1999), Bangs & Van Tyne (1931), Bucknill & Chasen (1990), Castelletta *et al.* (2000), Deignan (1945), Dickinson *et al.* (1991), Dodsworth (1911), Duckworth & Kelsch (1988), Duckworth *et al.* (1997), Eames & Robson (1992), Goes (1999), Grimmer *et al.* (1998), Harvey (1990), Holmes (1973), Inskipp, C.
